

Axion dark matters

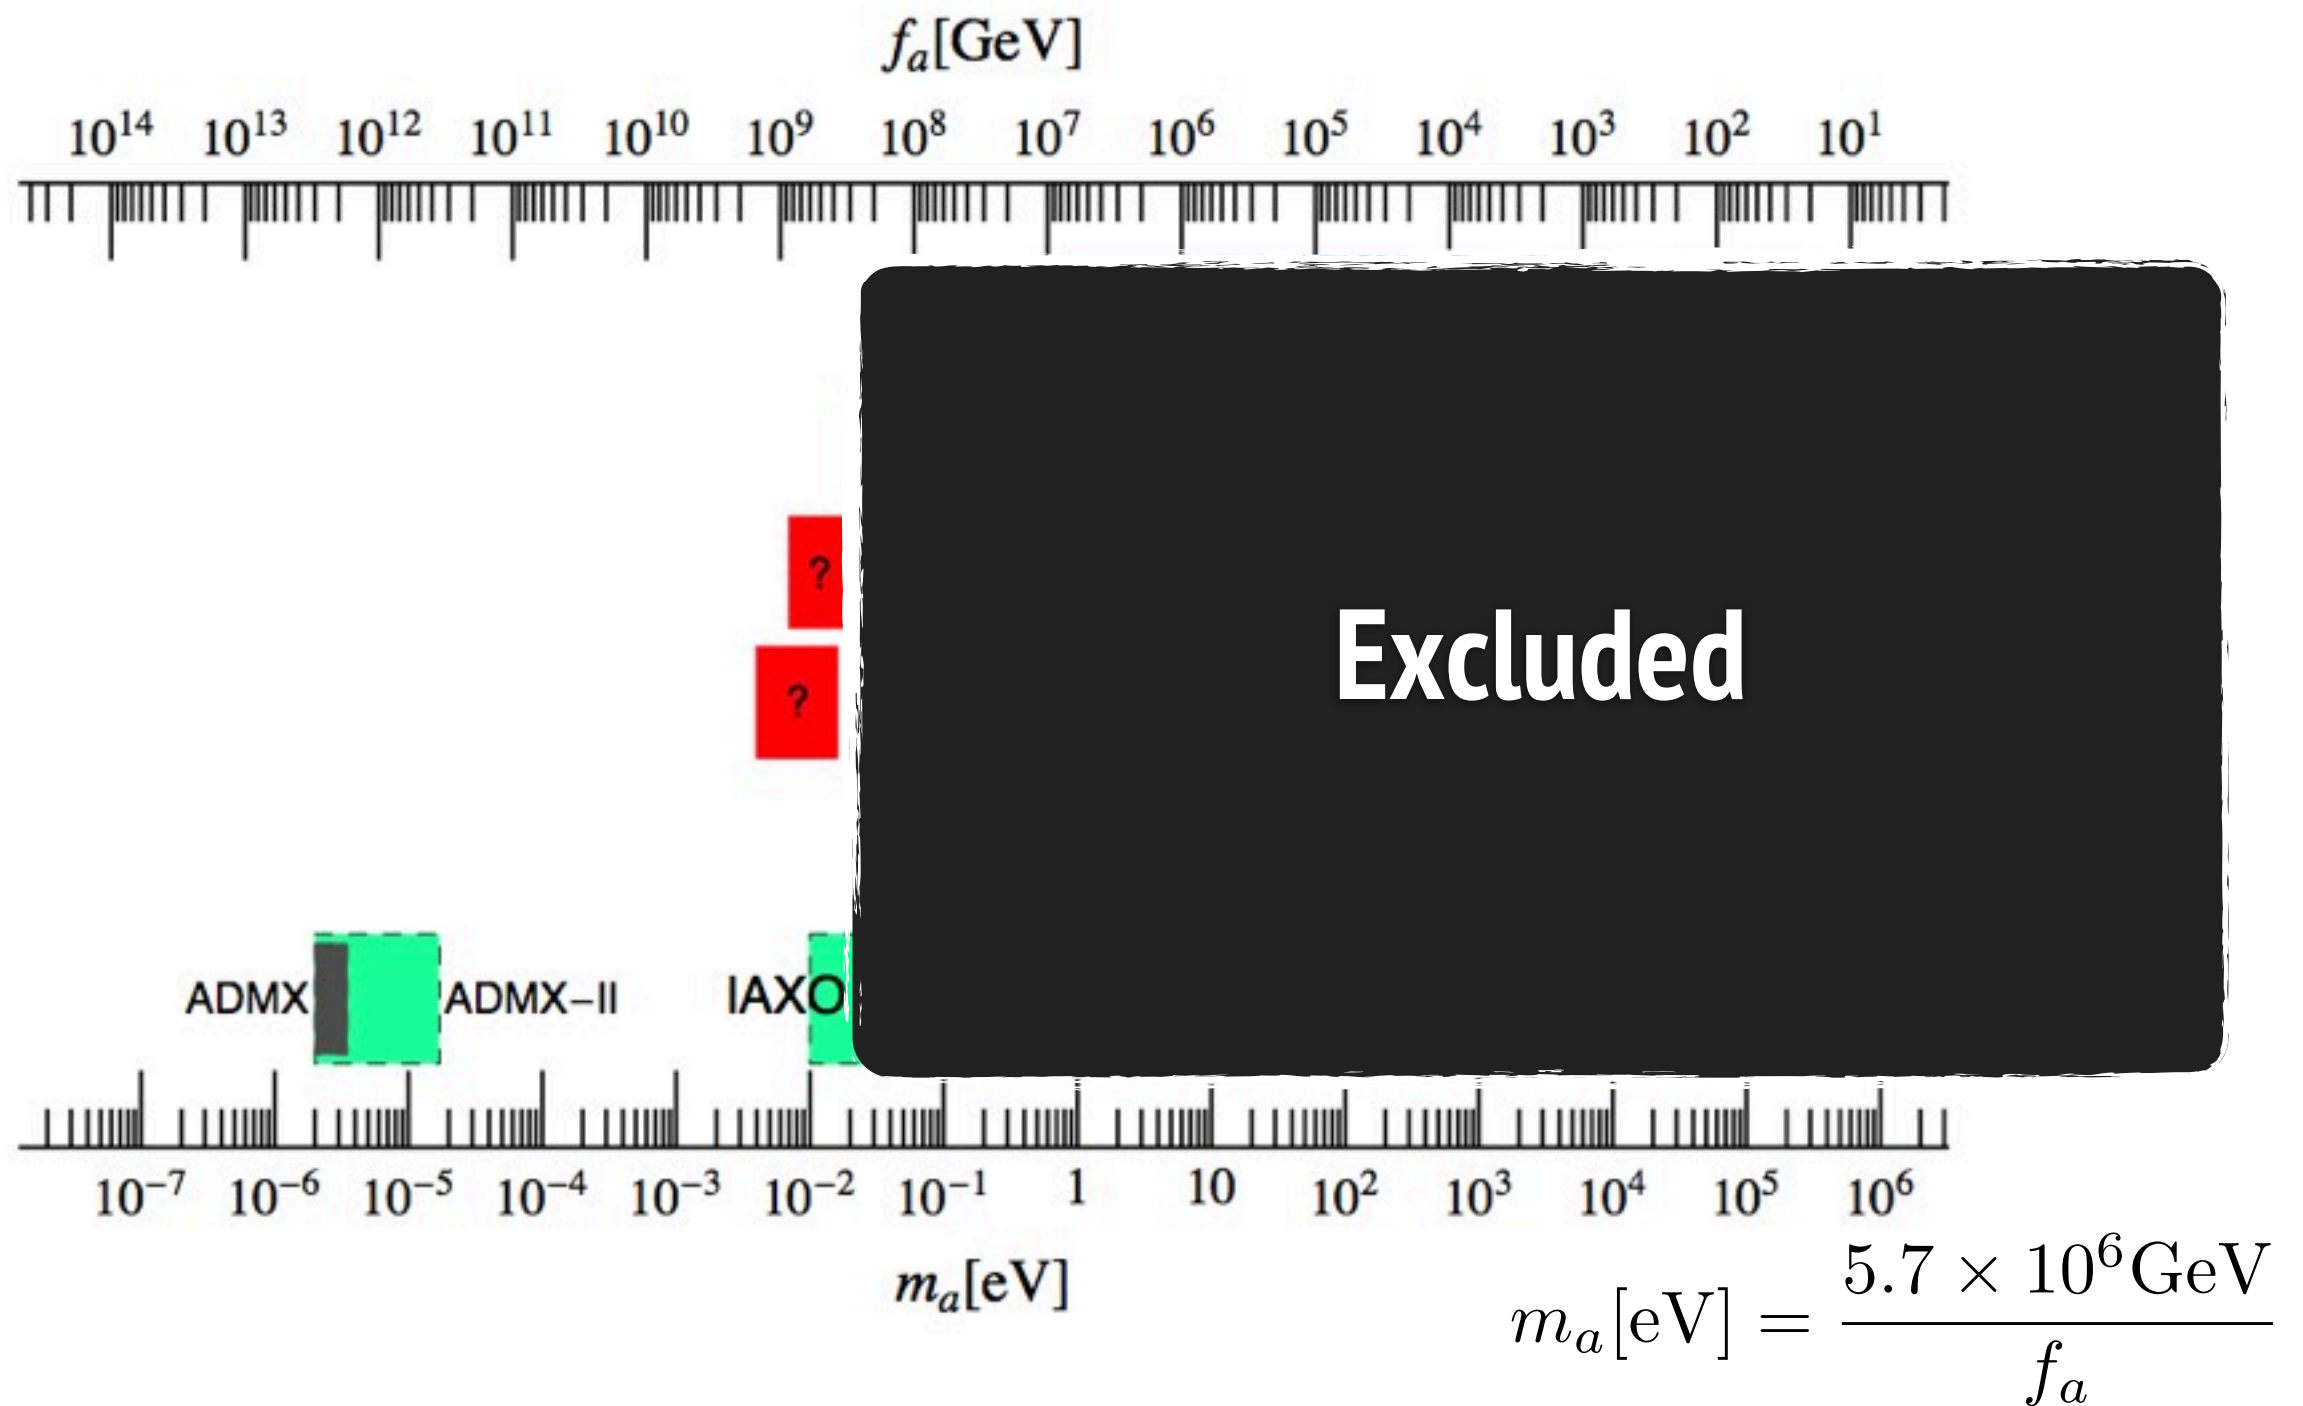

Landscape, what do we know?

$$m_a[\text{eV}] = \frac{5.7 \times 10^6 \text{ GeV}}{f_a}$$

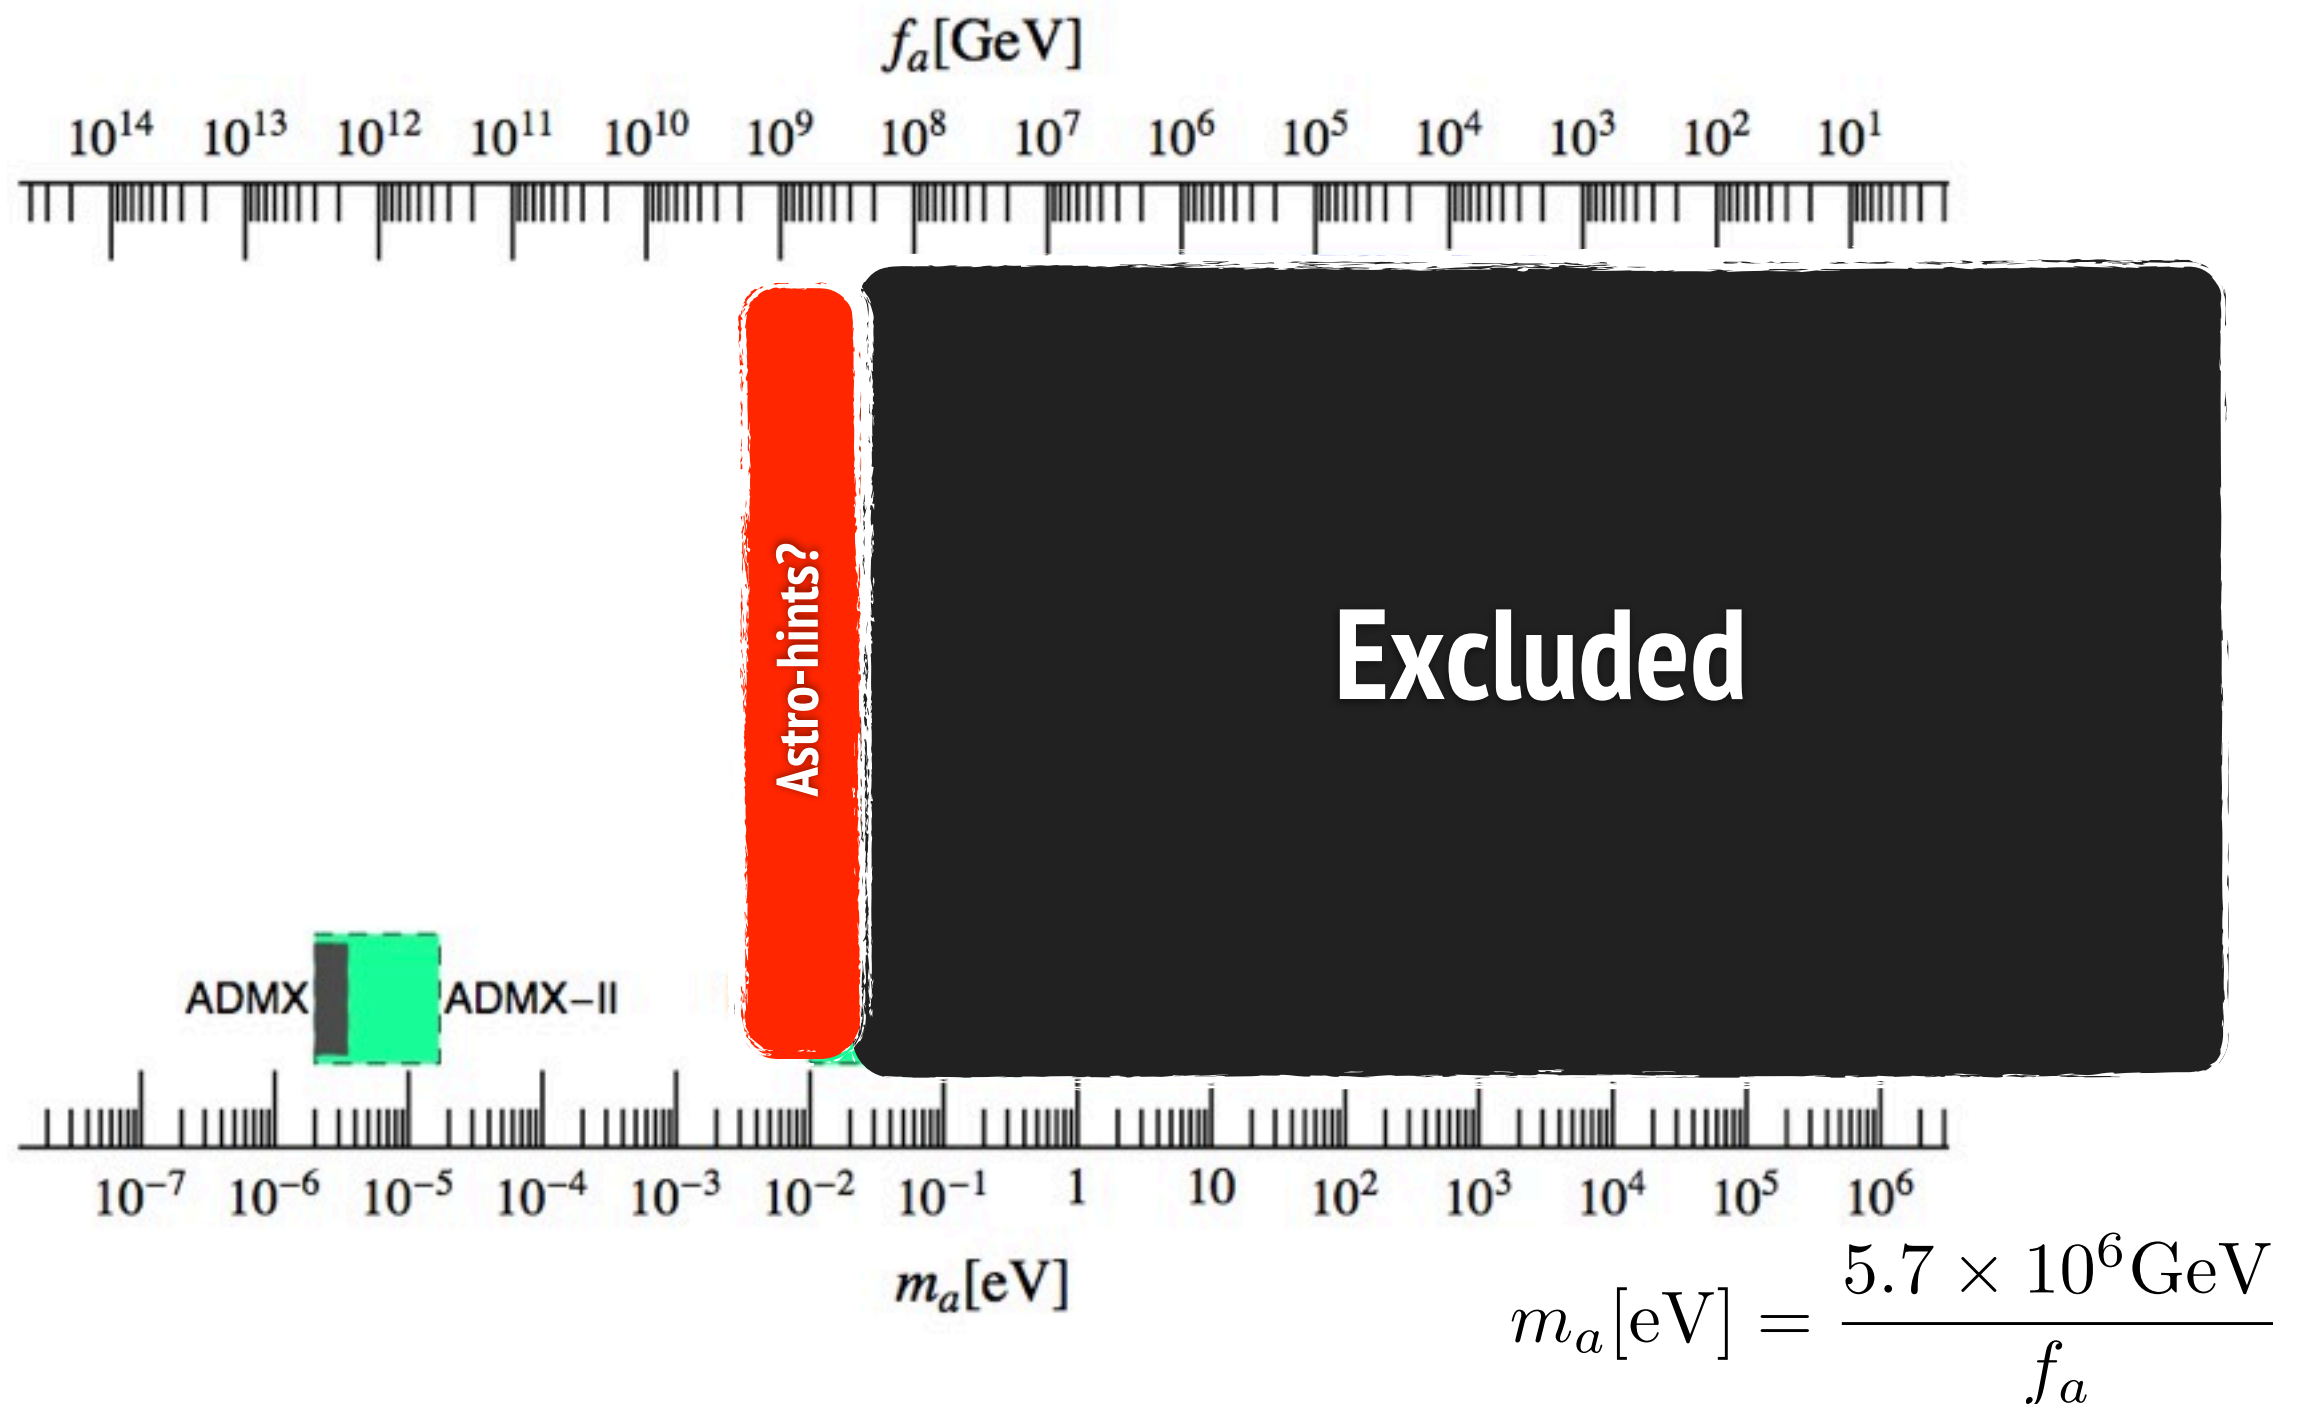

If axions exist, they are very light and VERY weakly interacting!

Landscape, what do we know?

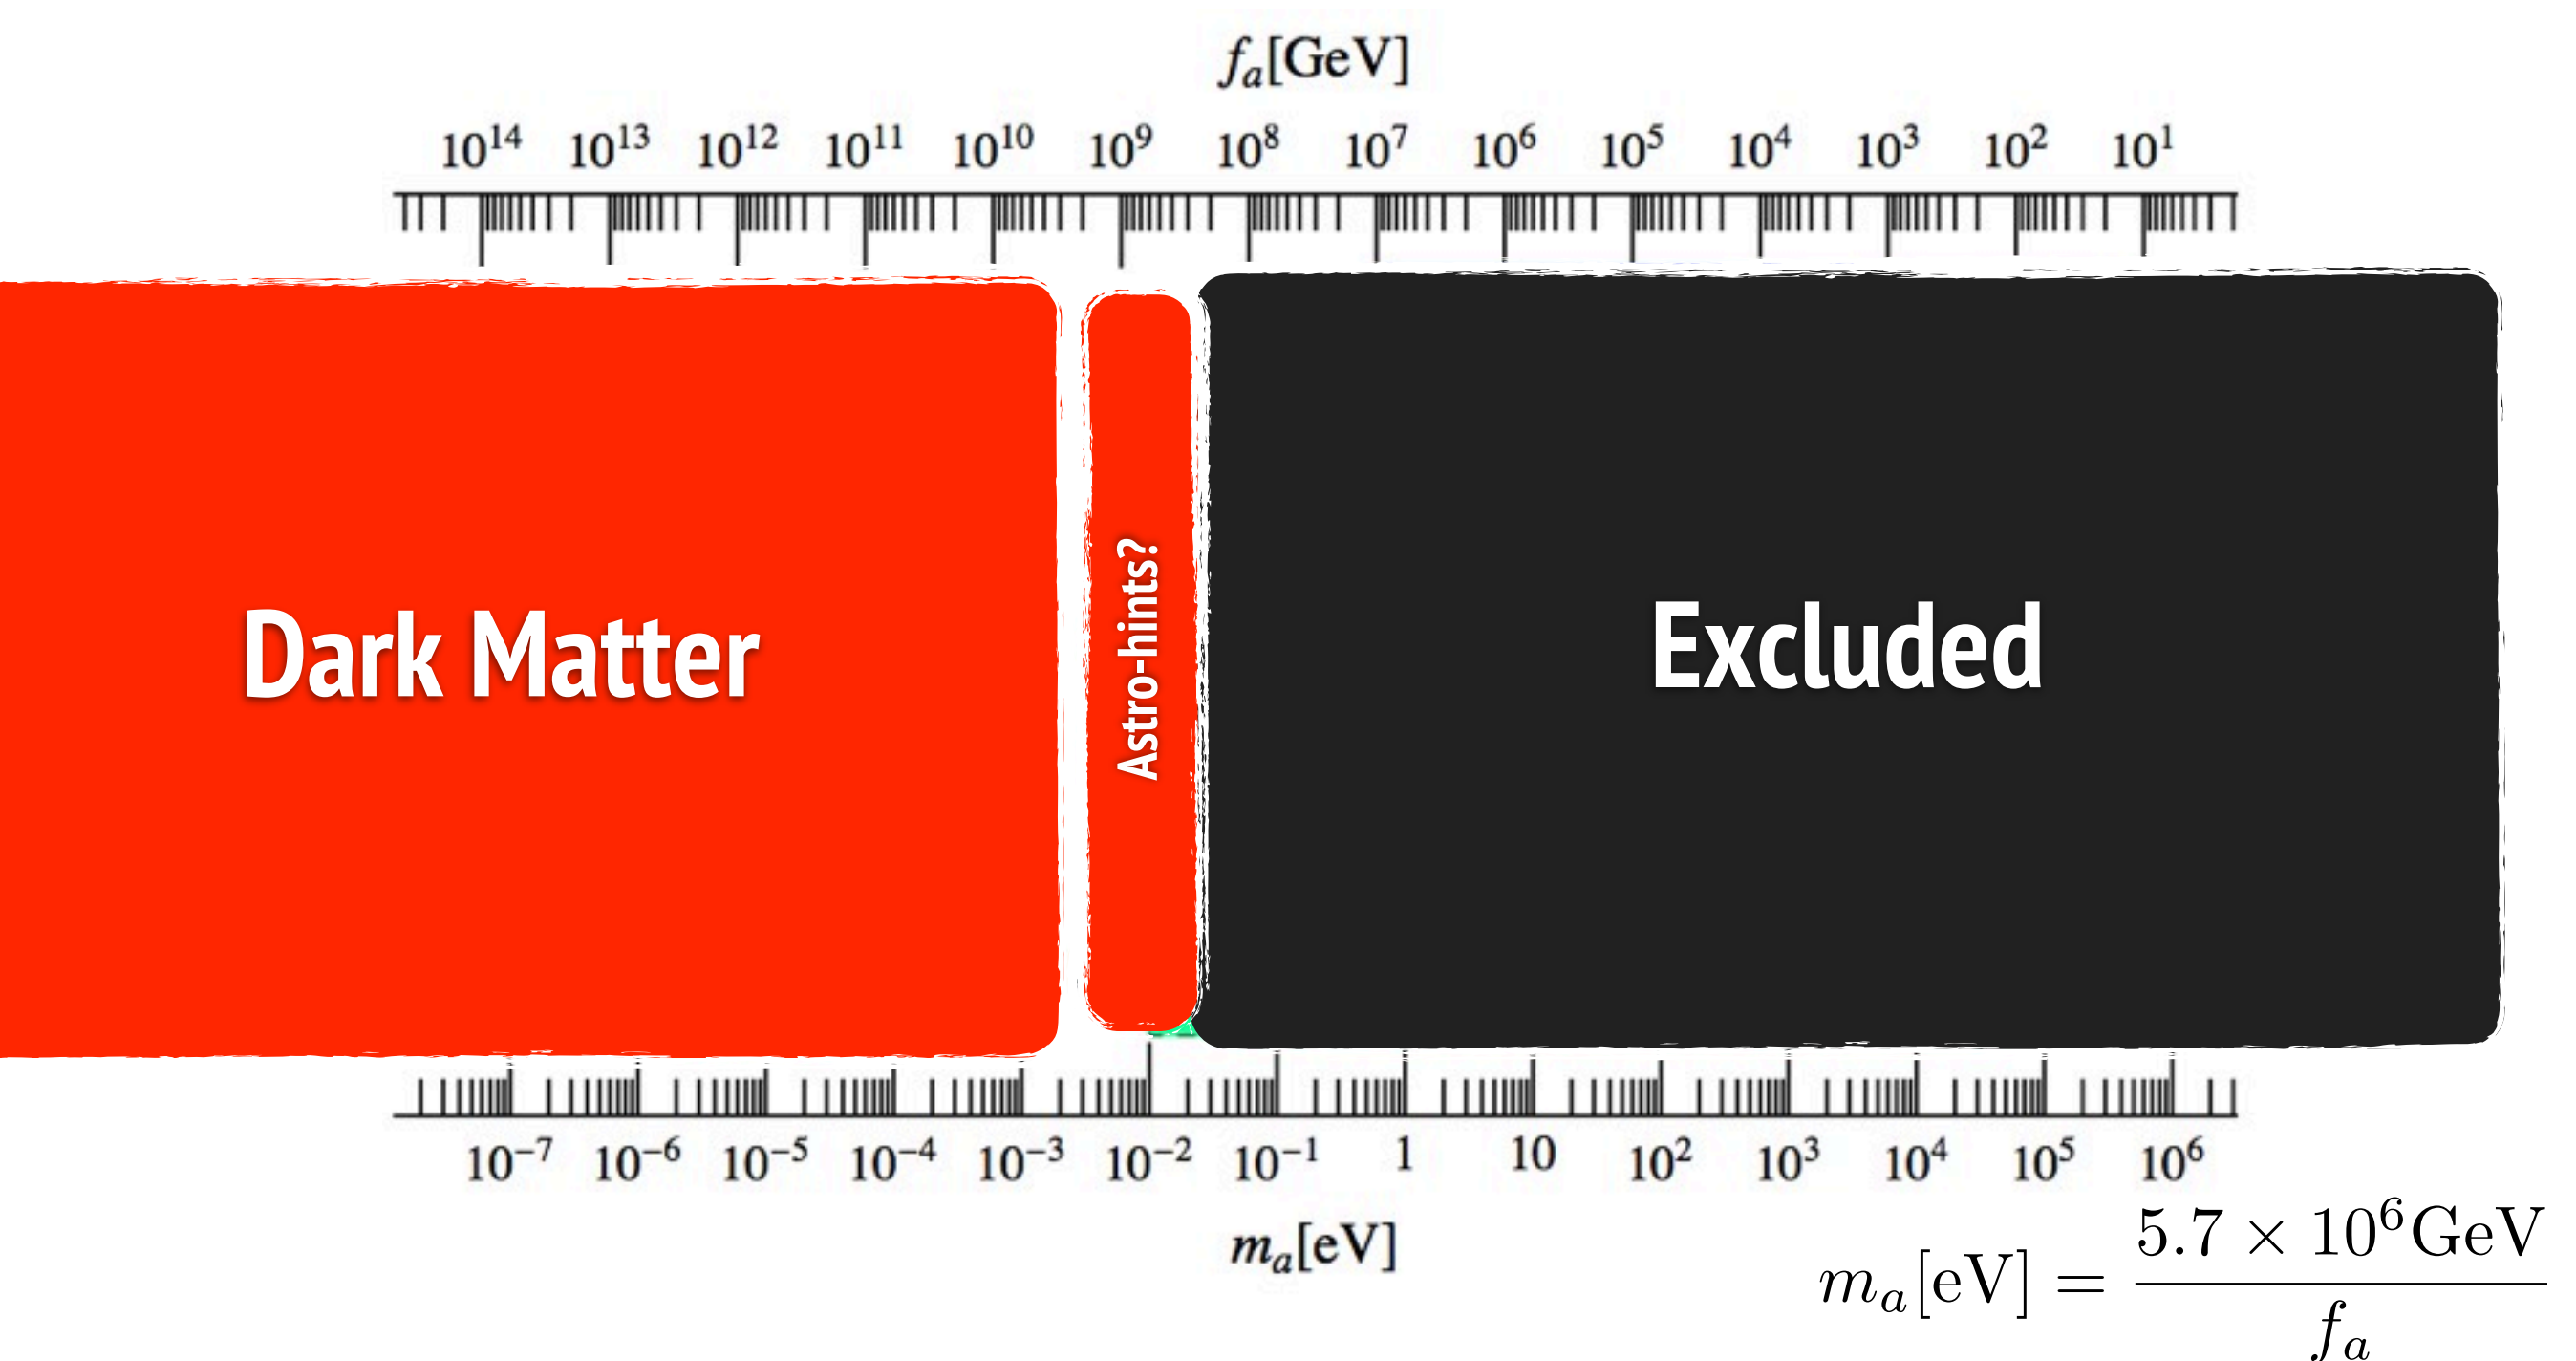

If axions exist, they are very light and VERY weakly interacting!

Landscape, what do we know?

If axions exist, they are very light and VERY weakly interacting!

Landscape, what do we know?

If axions exist, they are very light and VERY weakly interacting!

Axions

- theta is dynamical $\theta(t, \mathbf{x})$

Measured today $|\theta| < 10^{-10}$ (strong CP problem)

Axions imply dark matter

- theta is dynamical $\theta(t, \mathbf{x})$

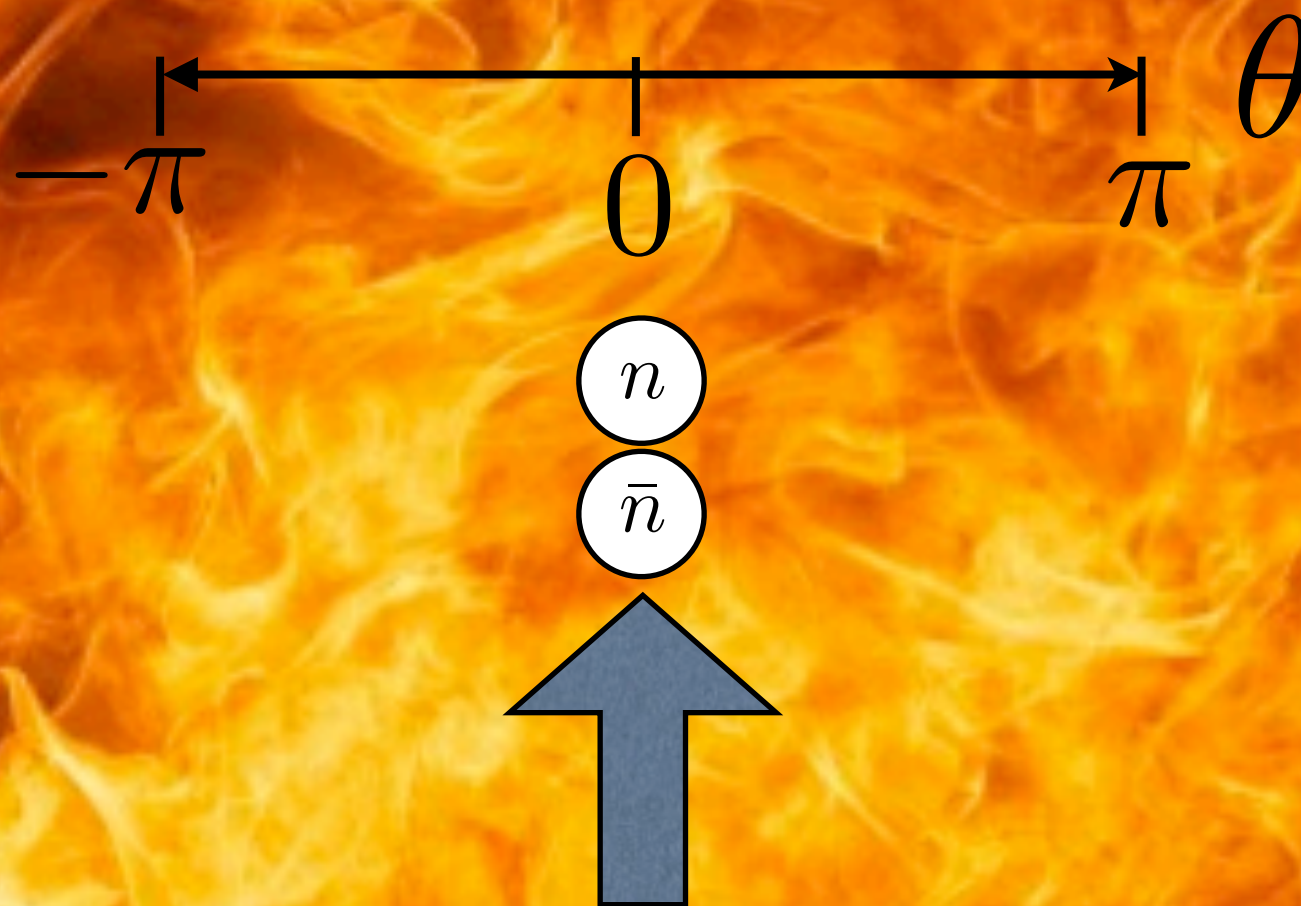

Initial conditions ?
= model-dependency

CP conserving

no preferred value at high Temperature ($T > \Lambda_{\text{QCD}}$)

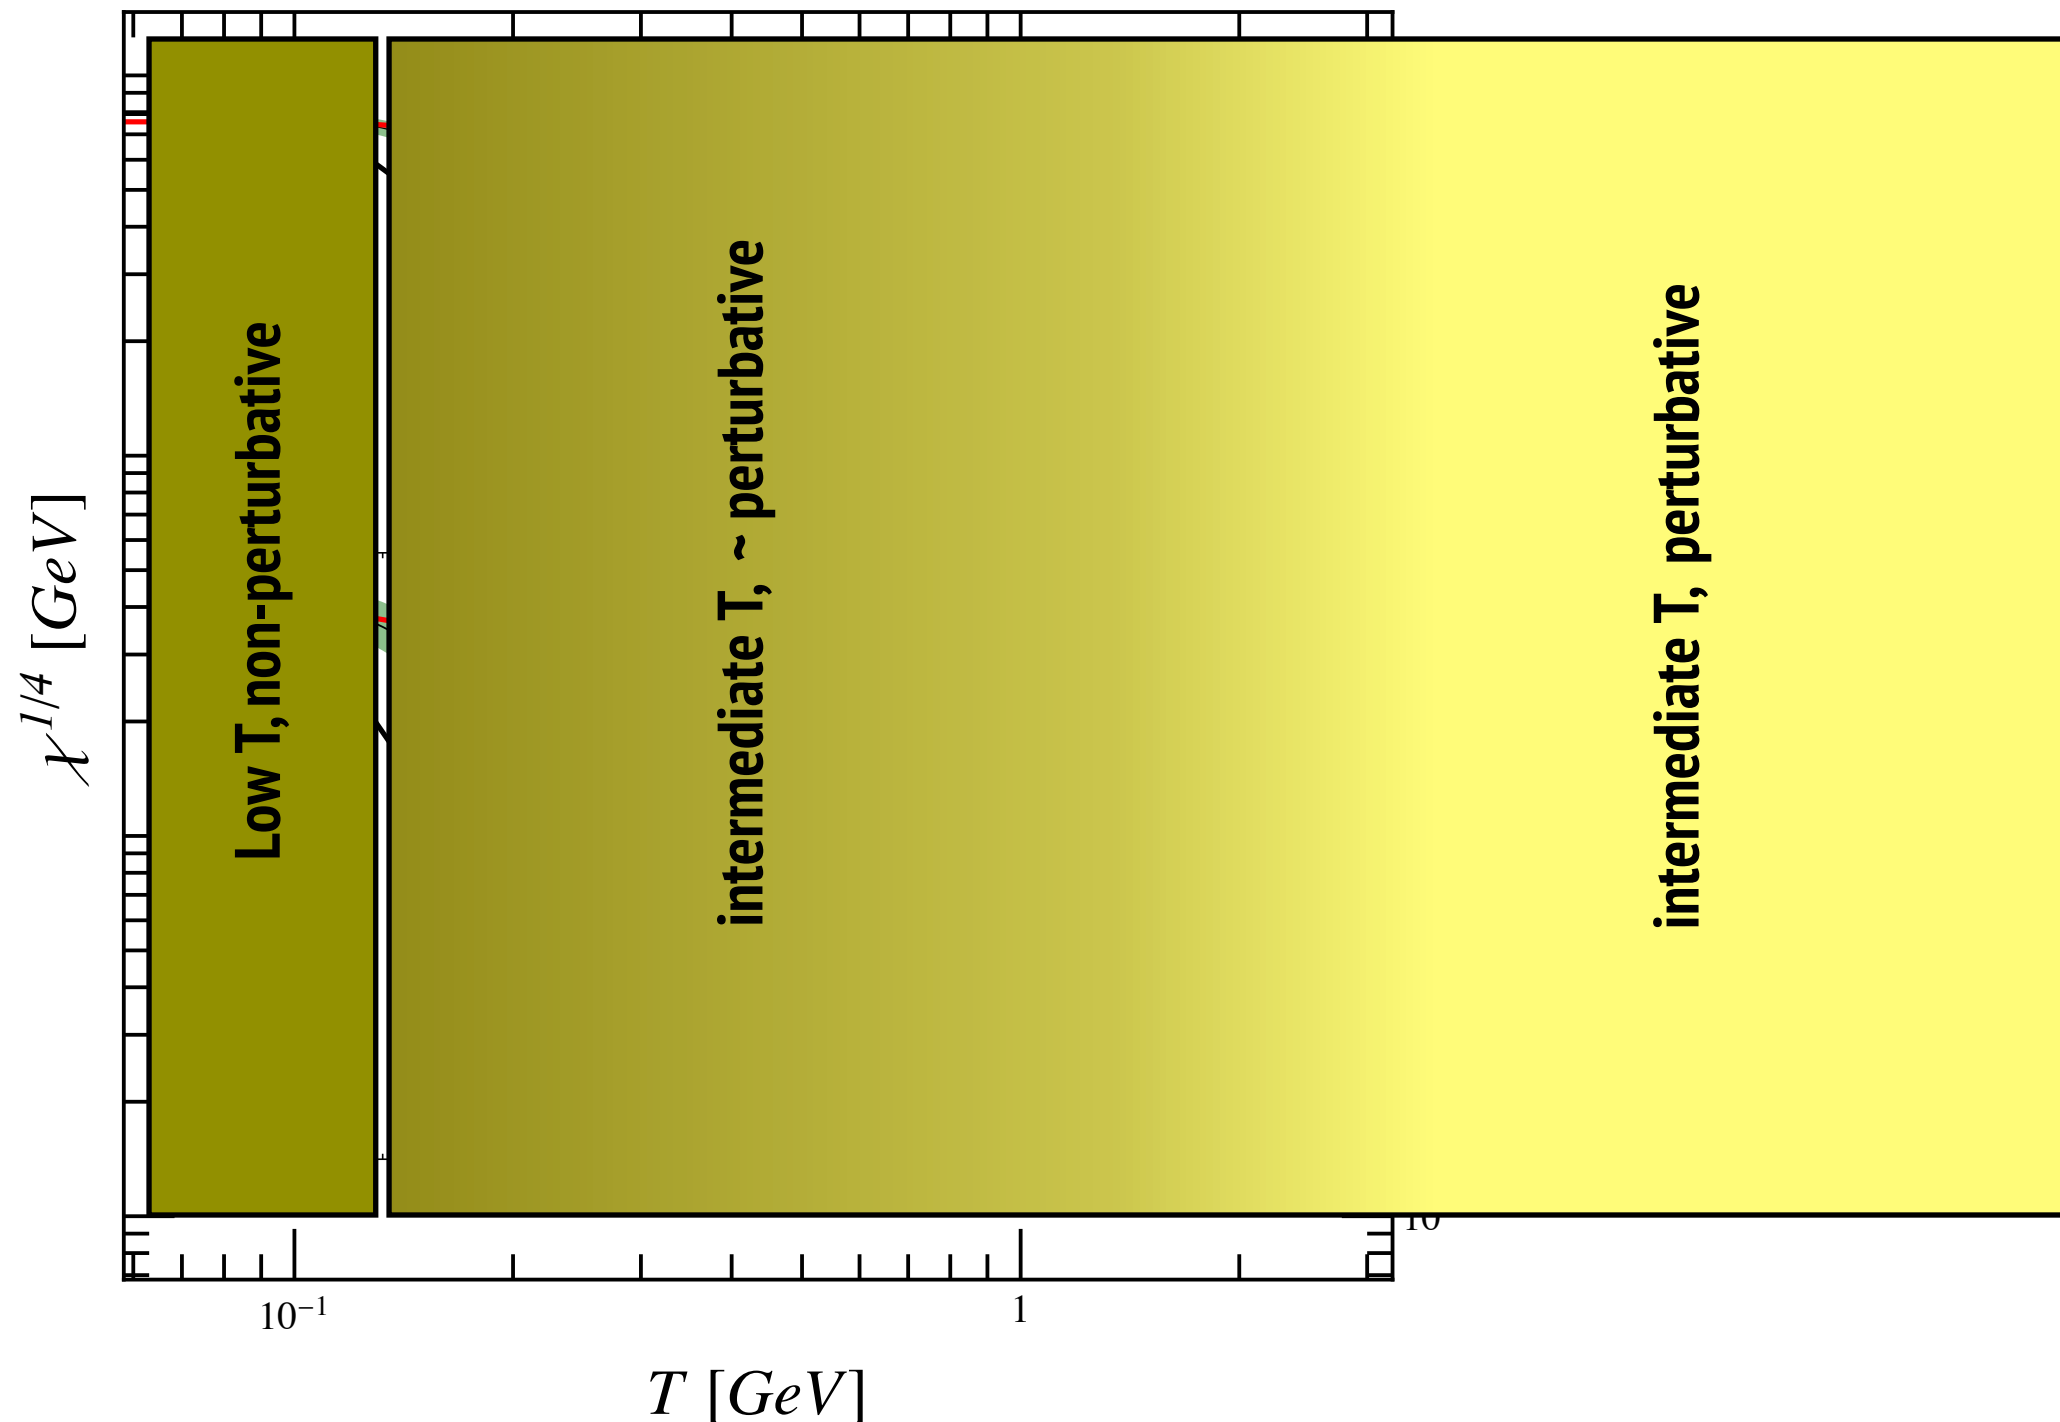

Measured today $|\theta| < 10^{-10}$ (strong CP problem)

Effective mass, lattice calculations

Axion mass/potential depend on non-perturbative QCD parameters $\langle \bar{q}q \rangle$, Λ^4

$T > T_c \sim 160$ MeV, running QCD coupling decreases, QCD becomes perturbative
quark condensate quickly disappears, Lambda also decreases

Effective mass, lattice calculations

Lattice QCD: we can compute axion mass

$$m_a^2 f_a^2 = \chi(T)$$

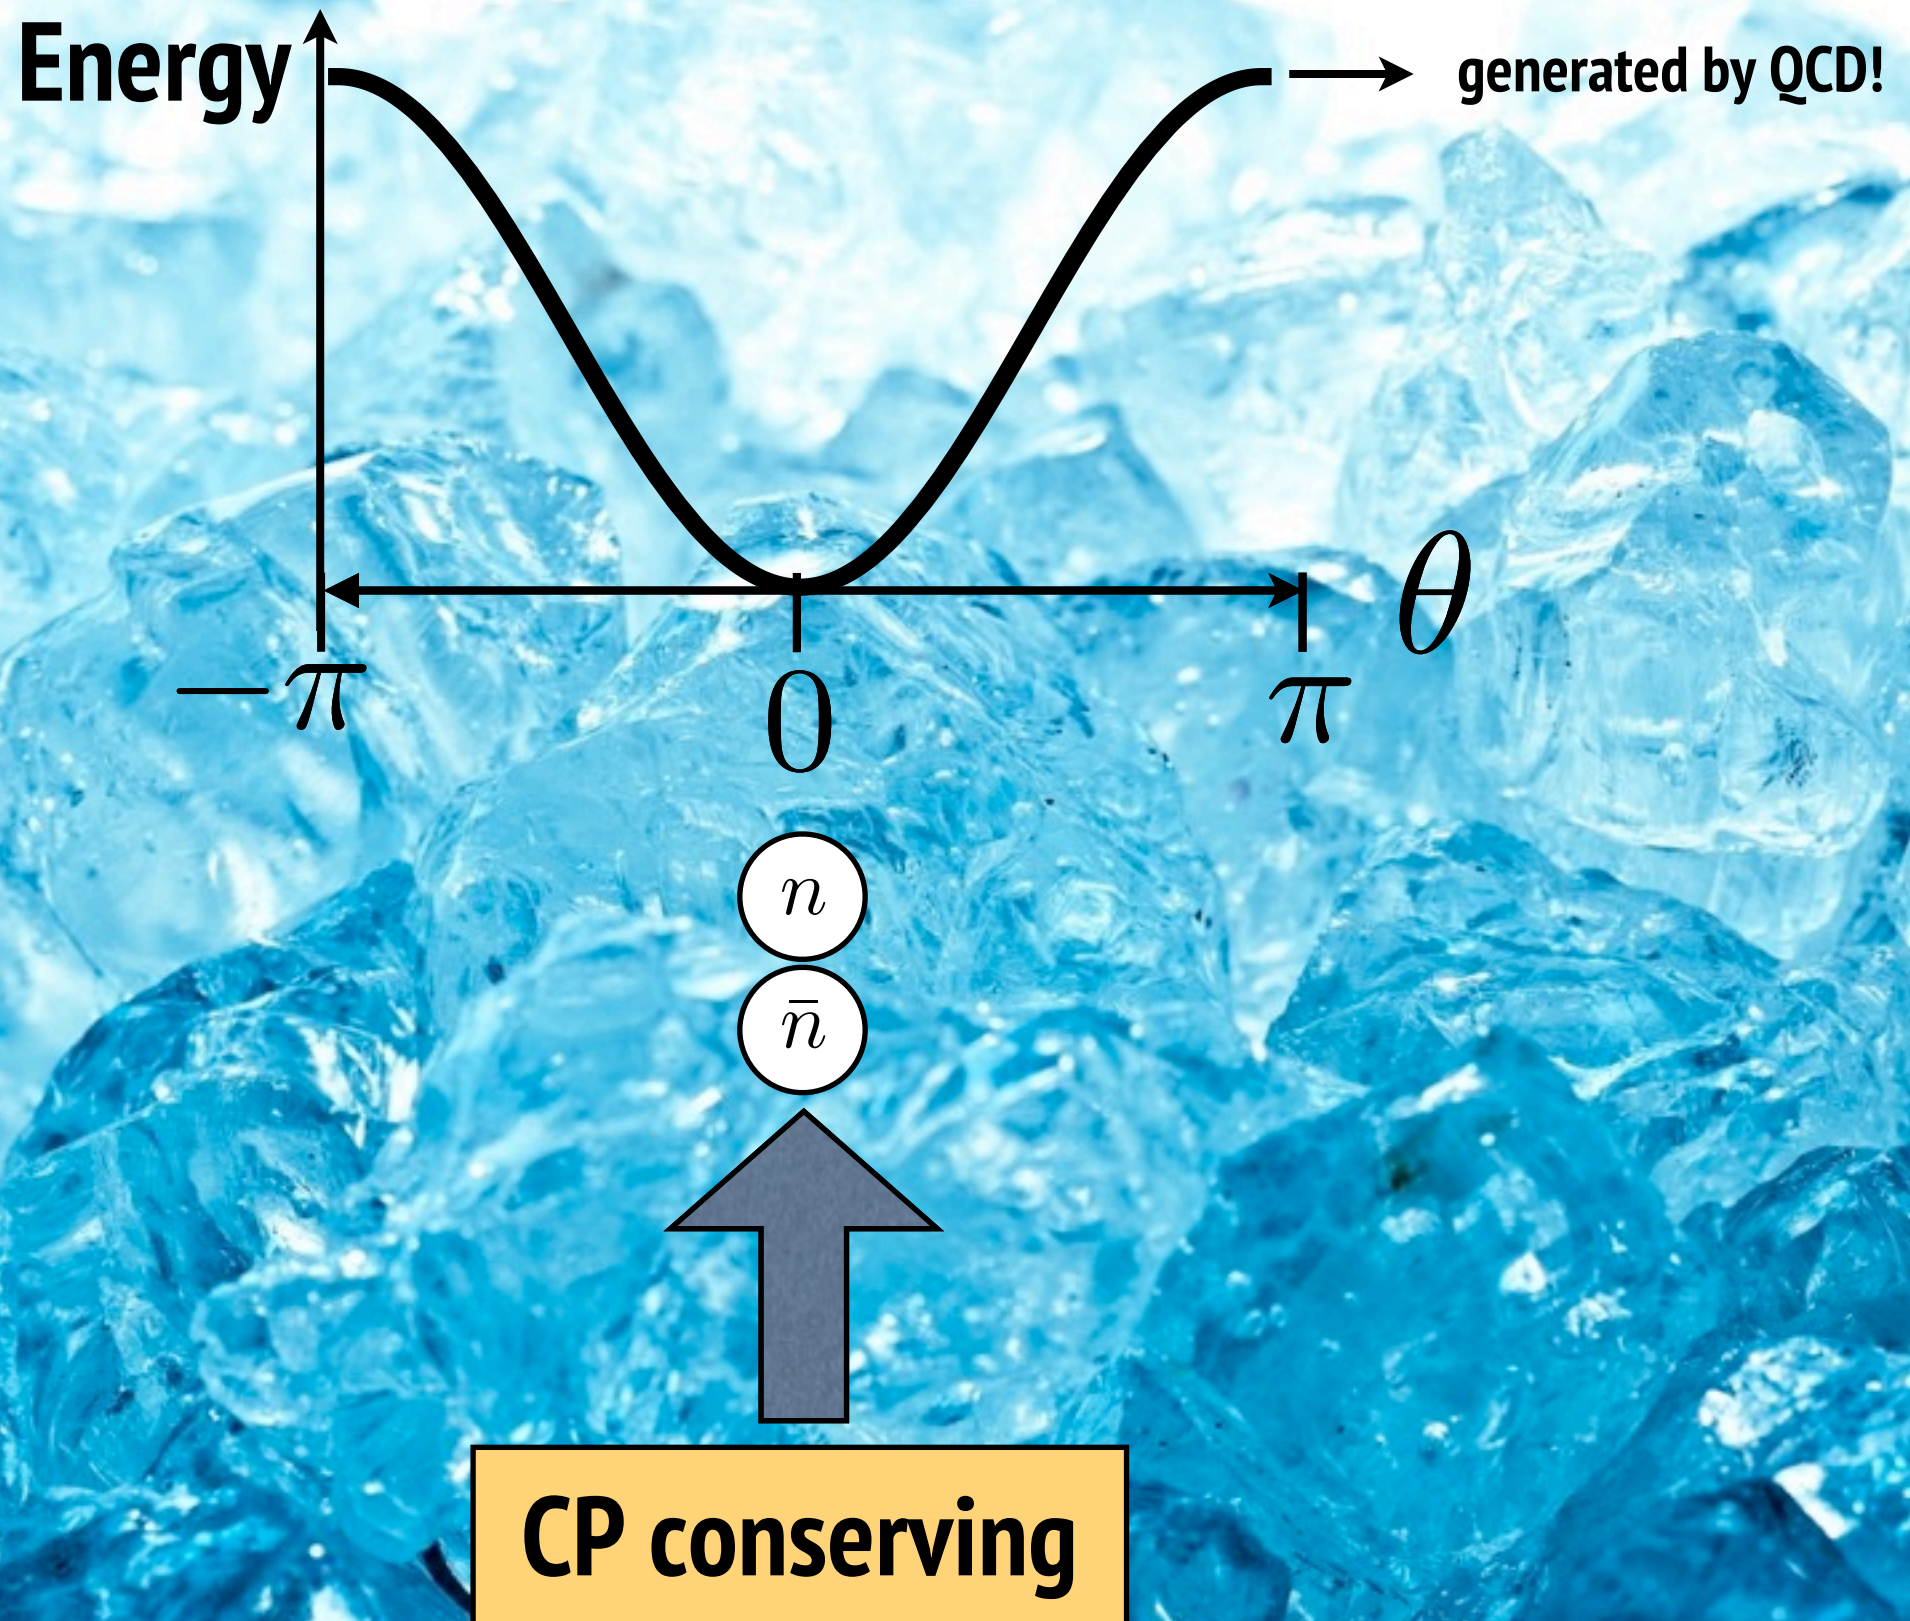

At high T (no mesons)

we can analytically compute potential (DIGA)

$$V(\theta) = -\chi(T) \cos \theta$$

below confinement, $\theta = 0$ minimises vacuum energy!

2 “typical” scenarios for initial conditions

- Initial conditions are cosmological and axion-model dependent

- Two typical (and extreme) scenarios are:

- random initial conditions
in patches of our Universe

- One common initial condition
for the whole Universe

After PQ phase transition, theta IC conditions
no-correlation beyond causal horizon

average over initial conditions! -> prediction!

Inflation after PQ phase transition...
one domain stretched beyond our horizon!

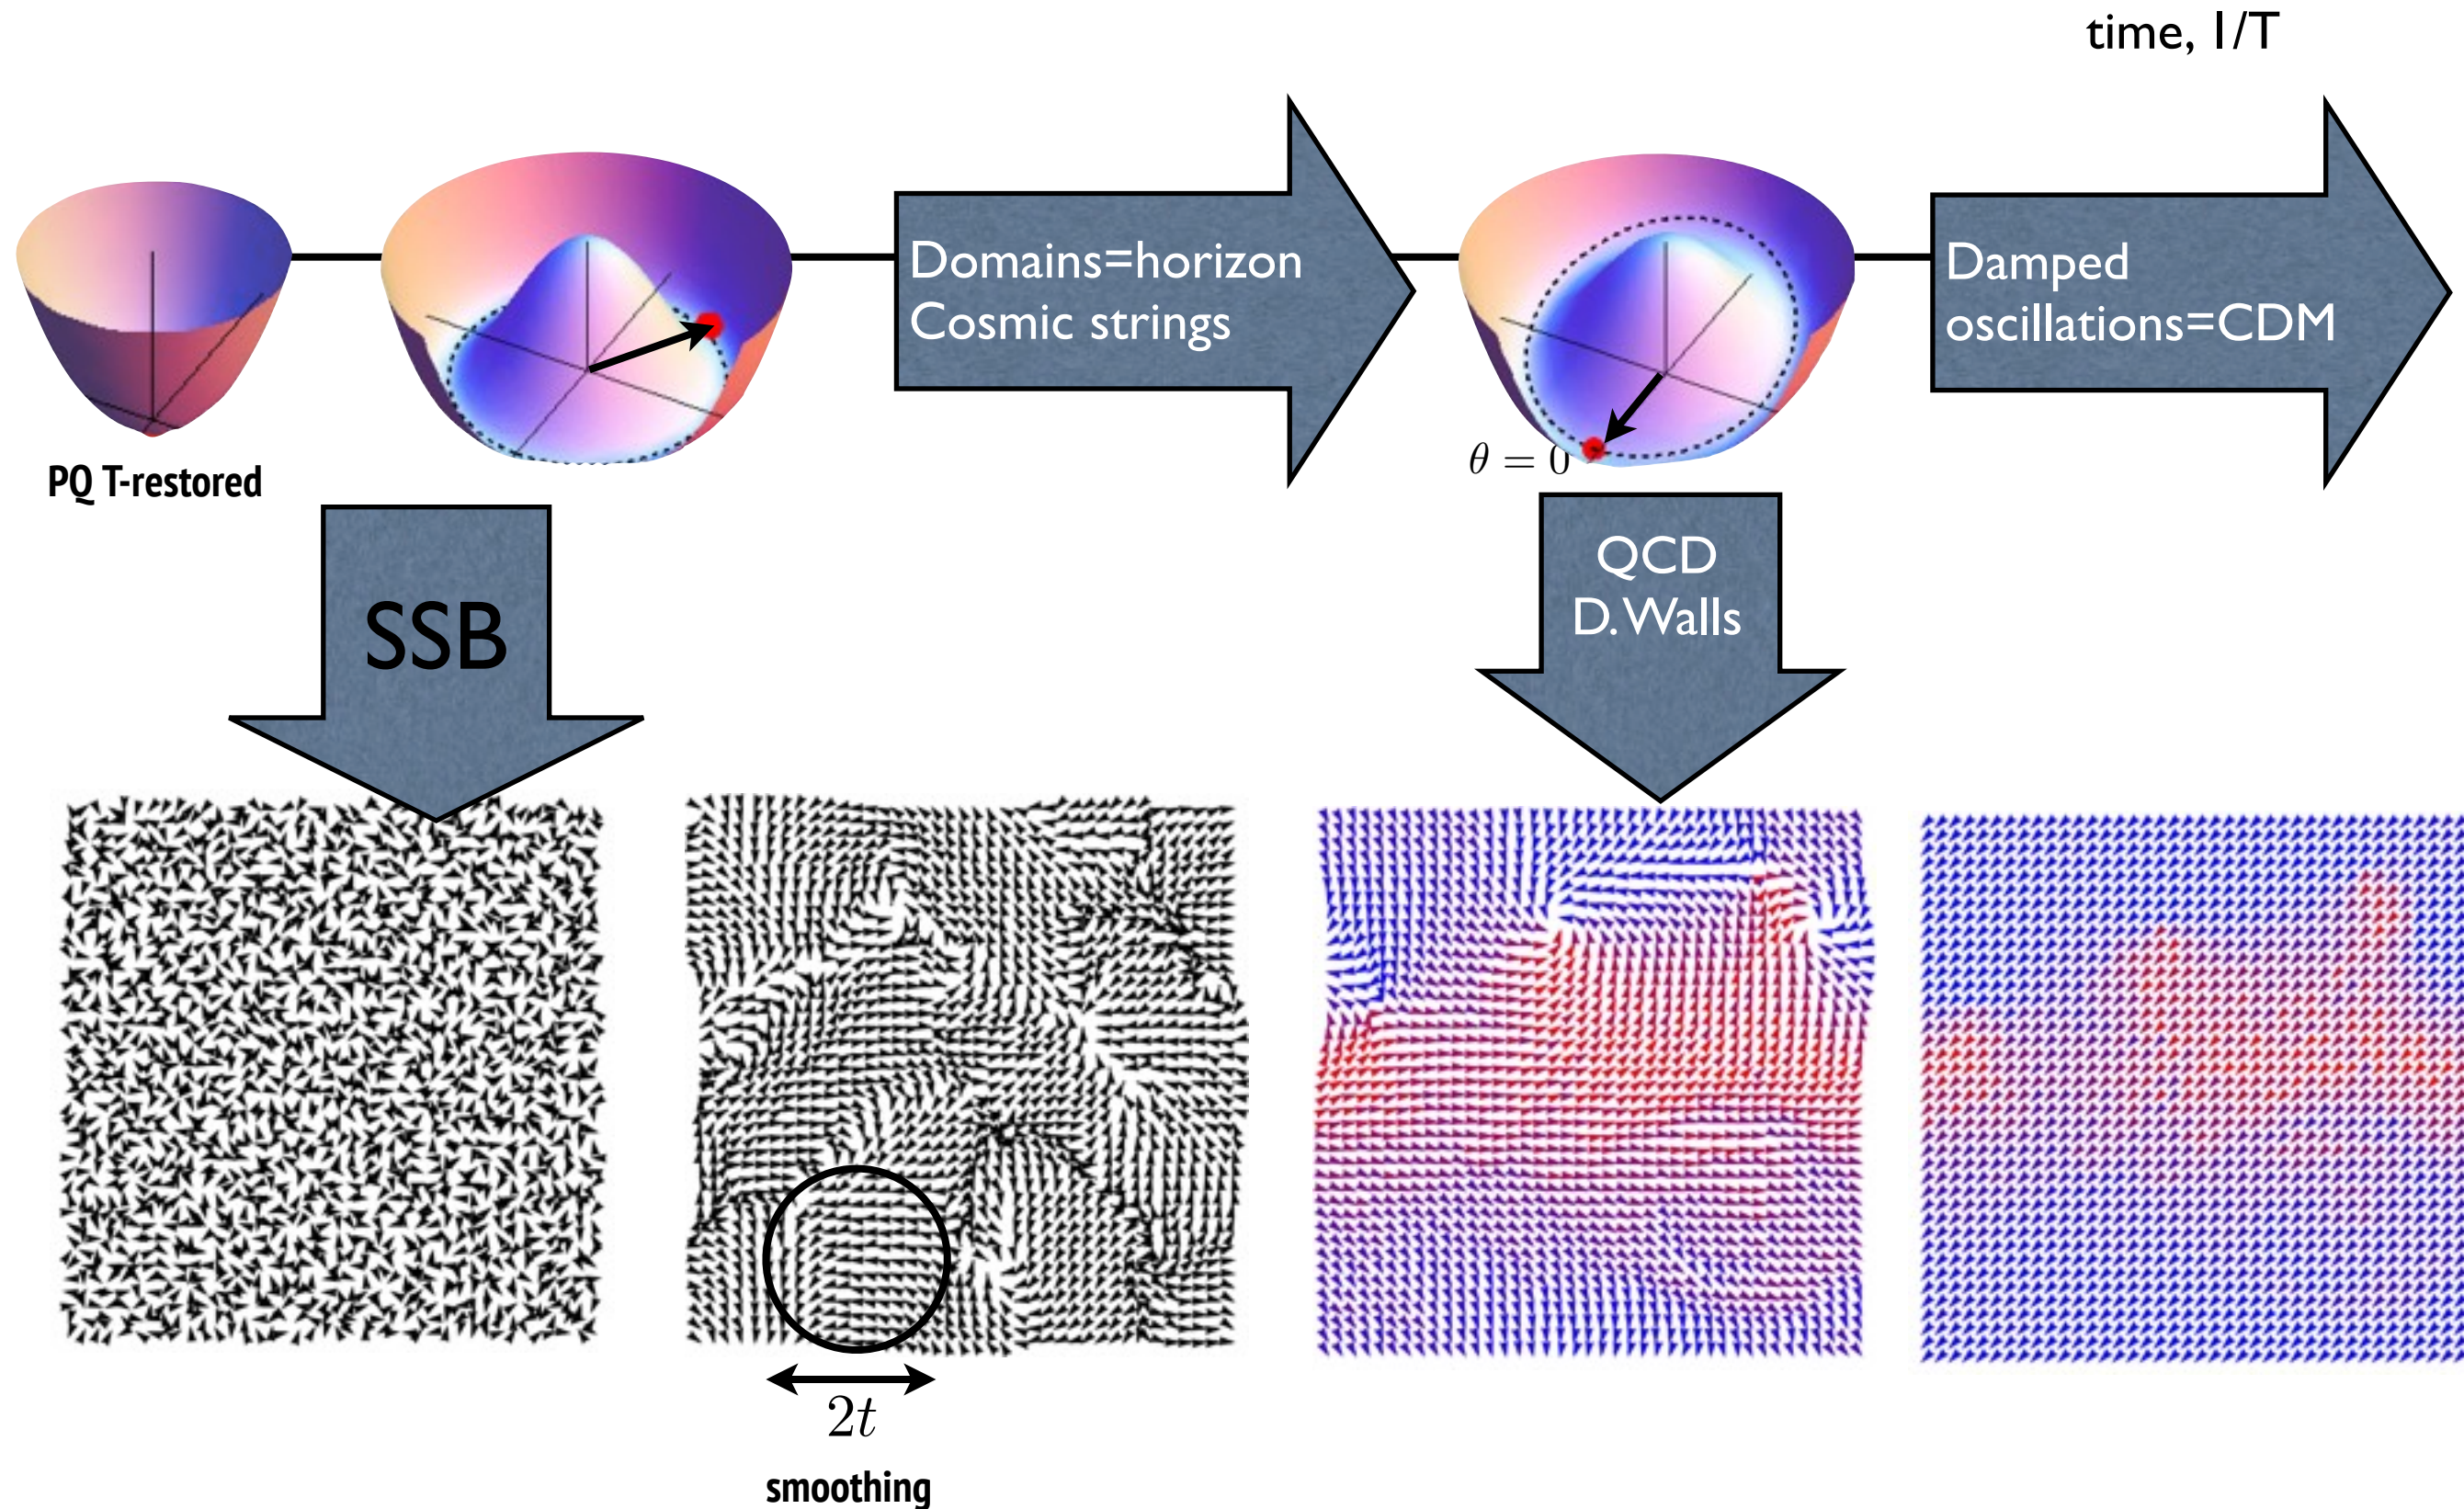

but which one???

$$\theta_I = ?$$

no prediction!

1st typical scenario: random initial conditions in our Universe

- Example KSVZ

1st typical scenario: random initial conditions in our Universe

- Example KSVZ

SSB

$2t$

smoothing

SCENARIO-I
realignment+CS+DWs
 $O(1)$ inhomogeneous DM

QCD
D. Walls

time, $1/T$

Damped oscillations=CDM

2nd typical scenario: 1 initial condition for our whole Universe

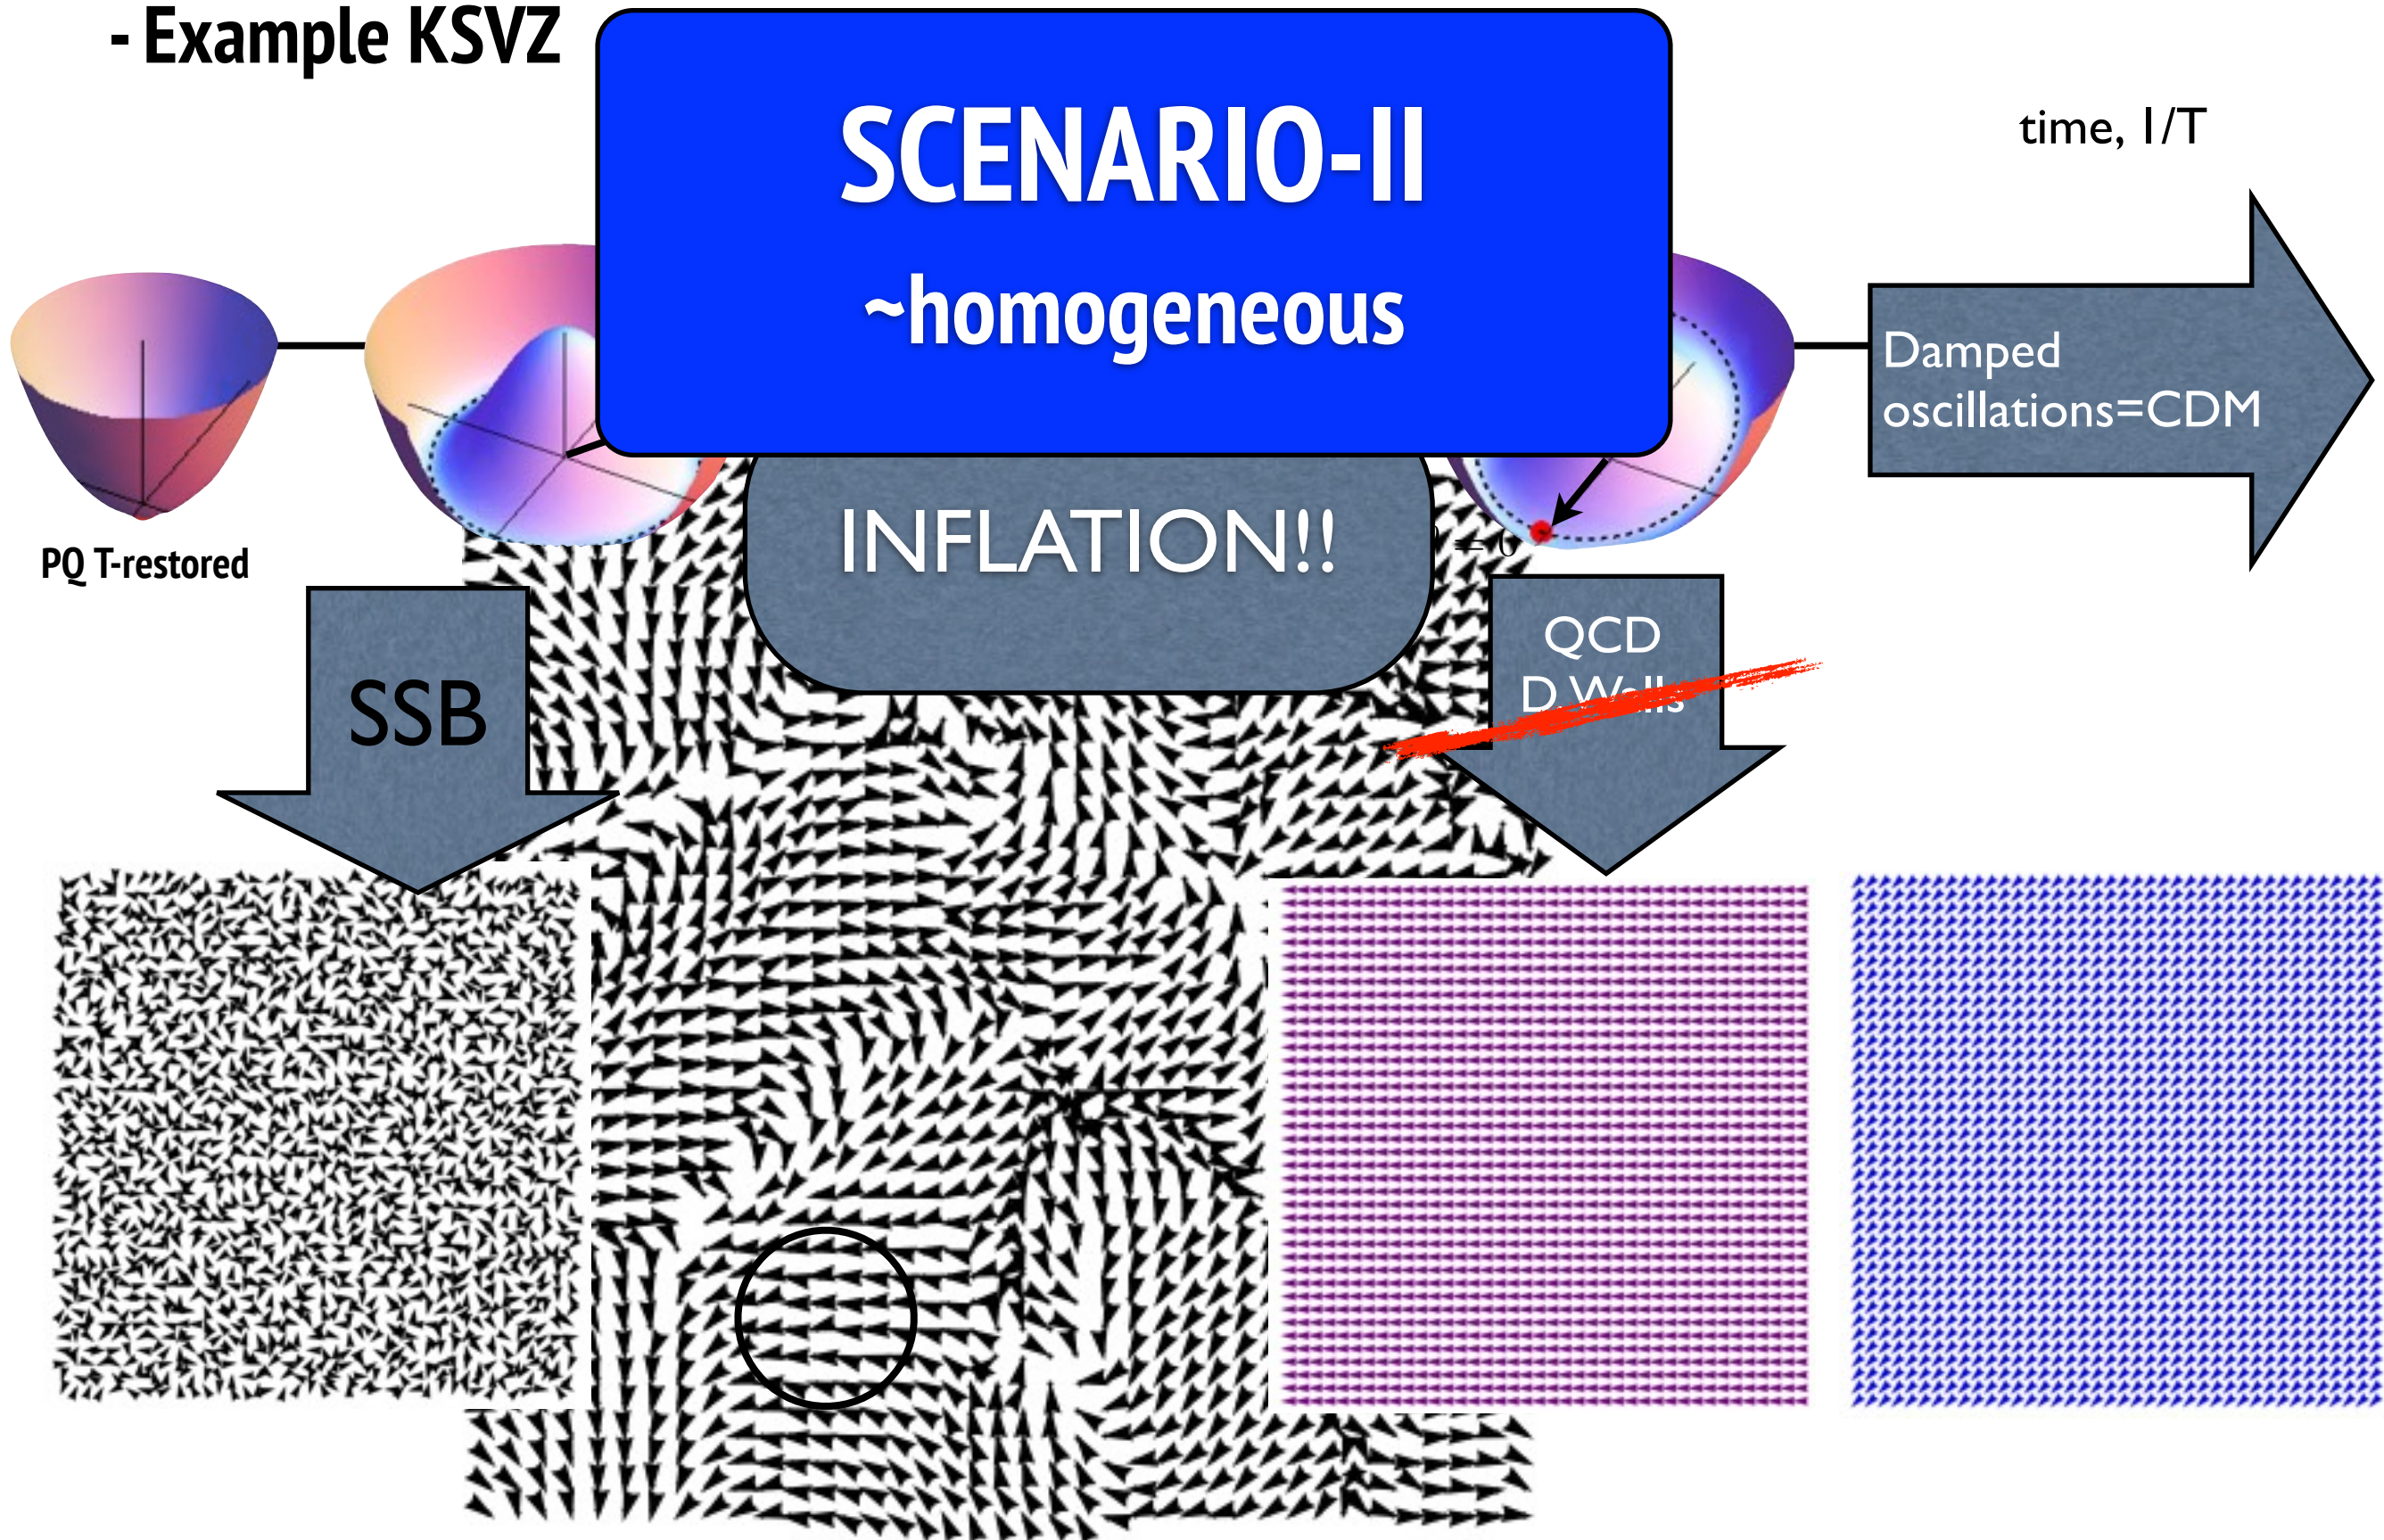

- Example KSVZ

time, $1/T$

2nd typical scenario: 1 initial condition for our whole Universe

- Example KSVZ

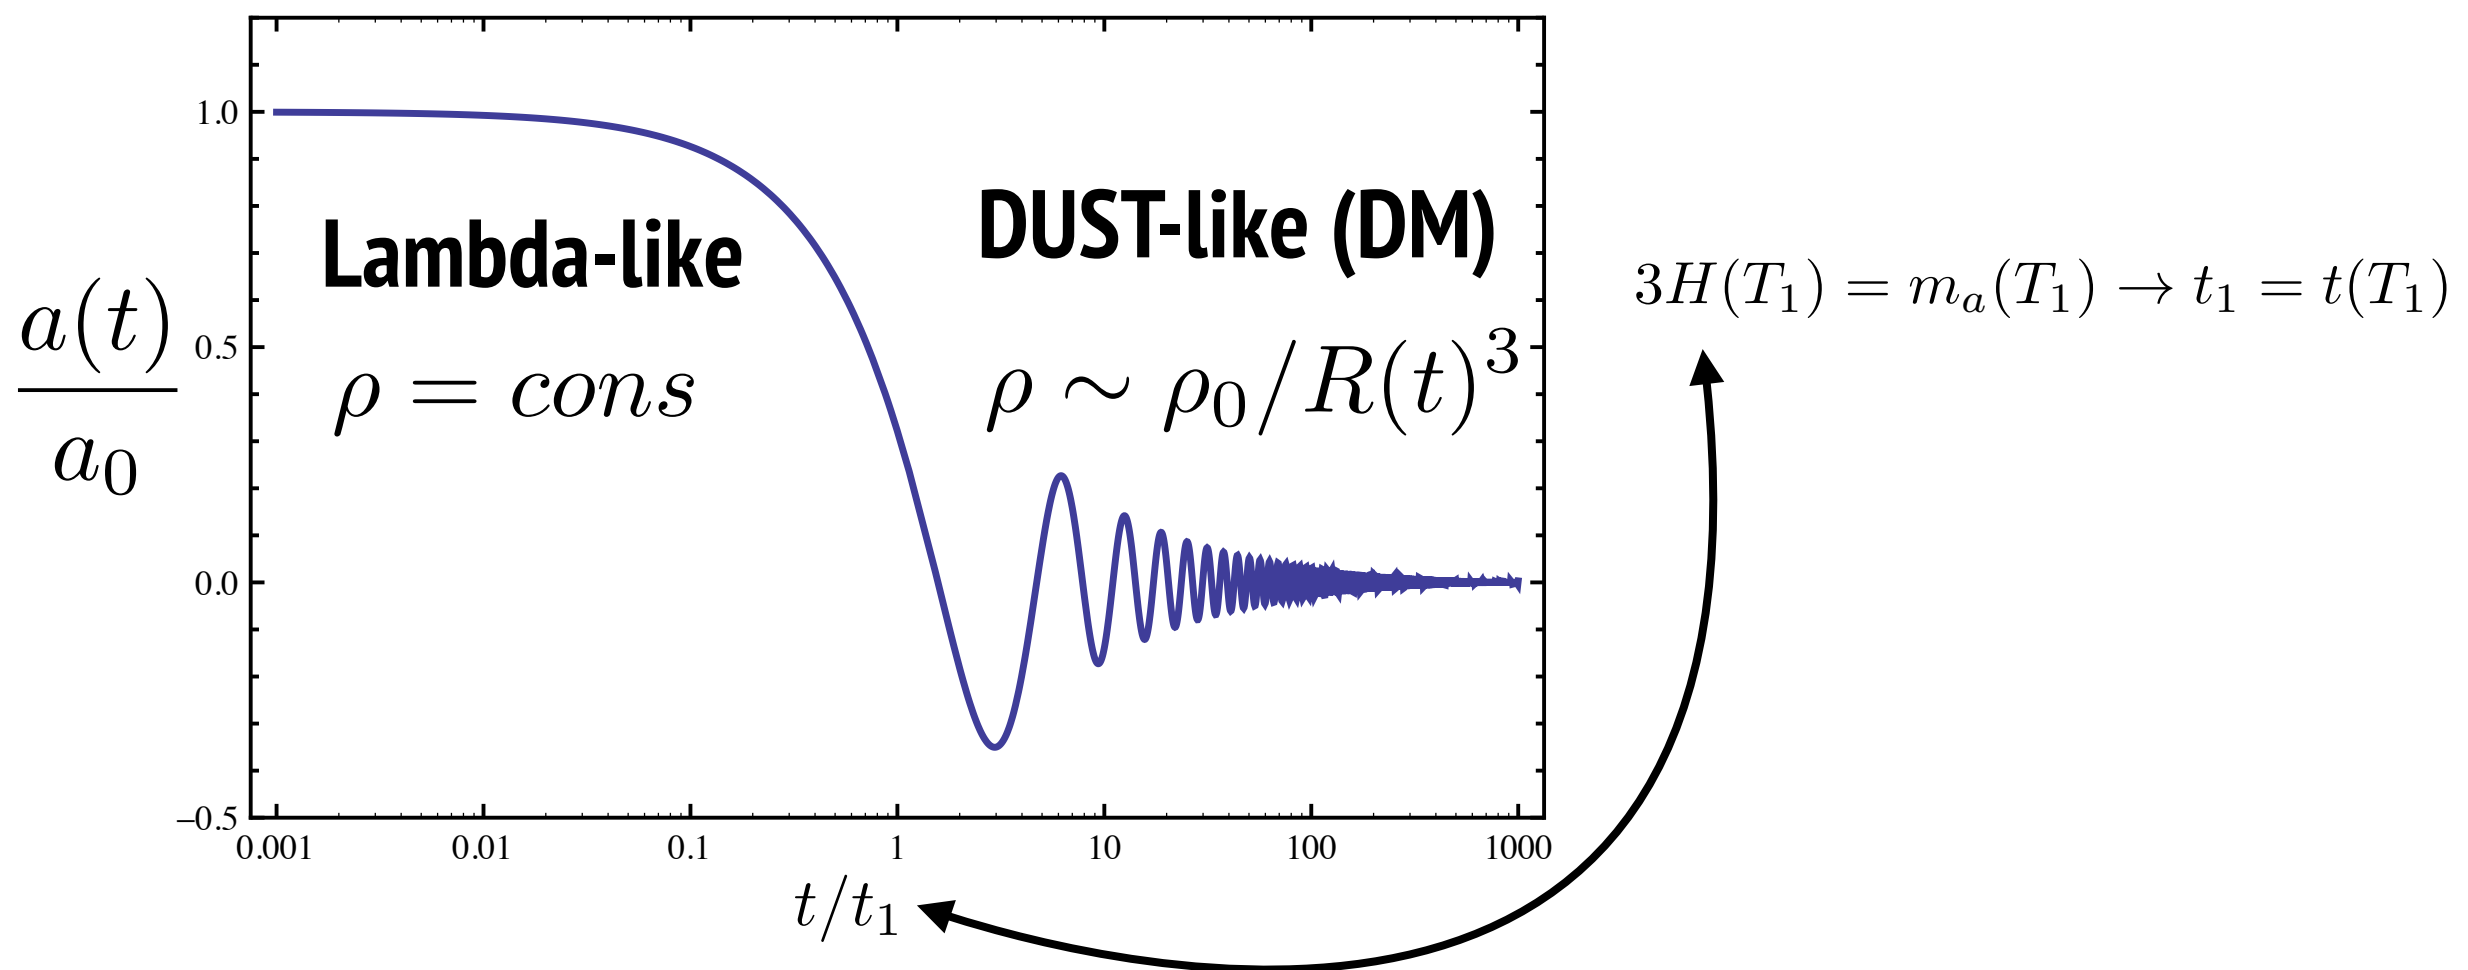

Axion Dark Matter Evolution (scenario 2)

Non-thermal, decoupled = Initial conditions + simple evolution

E.O.M. $\ddot{a} + 3H\dot{a} + m_a^2 a \simeq 0$ (SIMPLIFIED)

Energy density (harmonic osc) $\rho = \frac{1}{2}(\dot{a})^2 + \frac{1}{2}(\nabla a)^2 + V(\theta) \sim \frac{1}{2}(\dot{a})^2 + \frac{1}{2}m_a^2 a^2$

Note: No spatial dependence -> no momentum, no velocity (up to H)= ultracold dark matter

Axion dark matter

- The amount of axion DM produced depends on $m_a(f_a)$

$$H = \frac{1}{2t} \rightarrow t_1 \sim \frac{1}{m_a(T(t_1))} \propto f_a$$

- Axion starts to oscillate later, \sim initial energy \rightarrow more DM

Axion dark matter

- The amount of axion DM produced depends on f_a

$$H = \frac{1}{2t} \rightarrow t_1 \sim \frac{1}{m_a(T(t_1))} \propto f_a$$

- large f_a , small curvature, oscillations start later \rightarrow more DM

- small f_a , large curvature, oscillations start earlier \rightarrow less DM

Prob: Relic abundance calculation

DM density ($m_a \gg 3H$)

$$\rho_a \sim \frac{\rho_1}{m_a(t_1)} m_a(t) \left(\frac{R_1}{R(t)} \right)^3$$

$$\rho_1 \sim \frac{1}{2} m_a^2(t_1) f_a^2 \theta_1^2$$

initial number density, mass, dilution due to
Universe expansion

$$H^2 = \frac{8\pi}{M_p^2} \frac{\pi^2}{30} g_* T^4$$

$$3H(T_1) = m_a(T_1) \rightarrow t_1 = t(T_1) \rightarrow T_1$$

$$m_a^2 = \chi(T) / f_a^2$$

Entropy conservation from T1 until now

$$g_S(T) (RT)^3 = \text{cons}$$

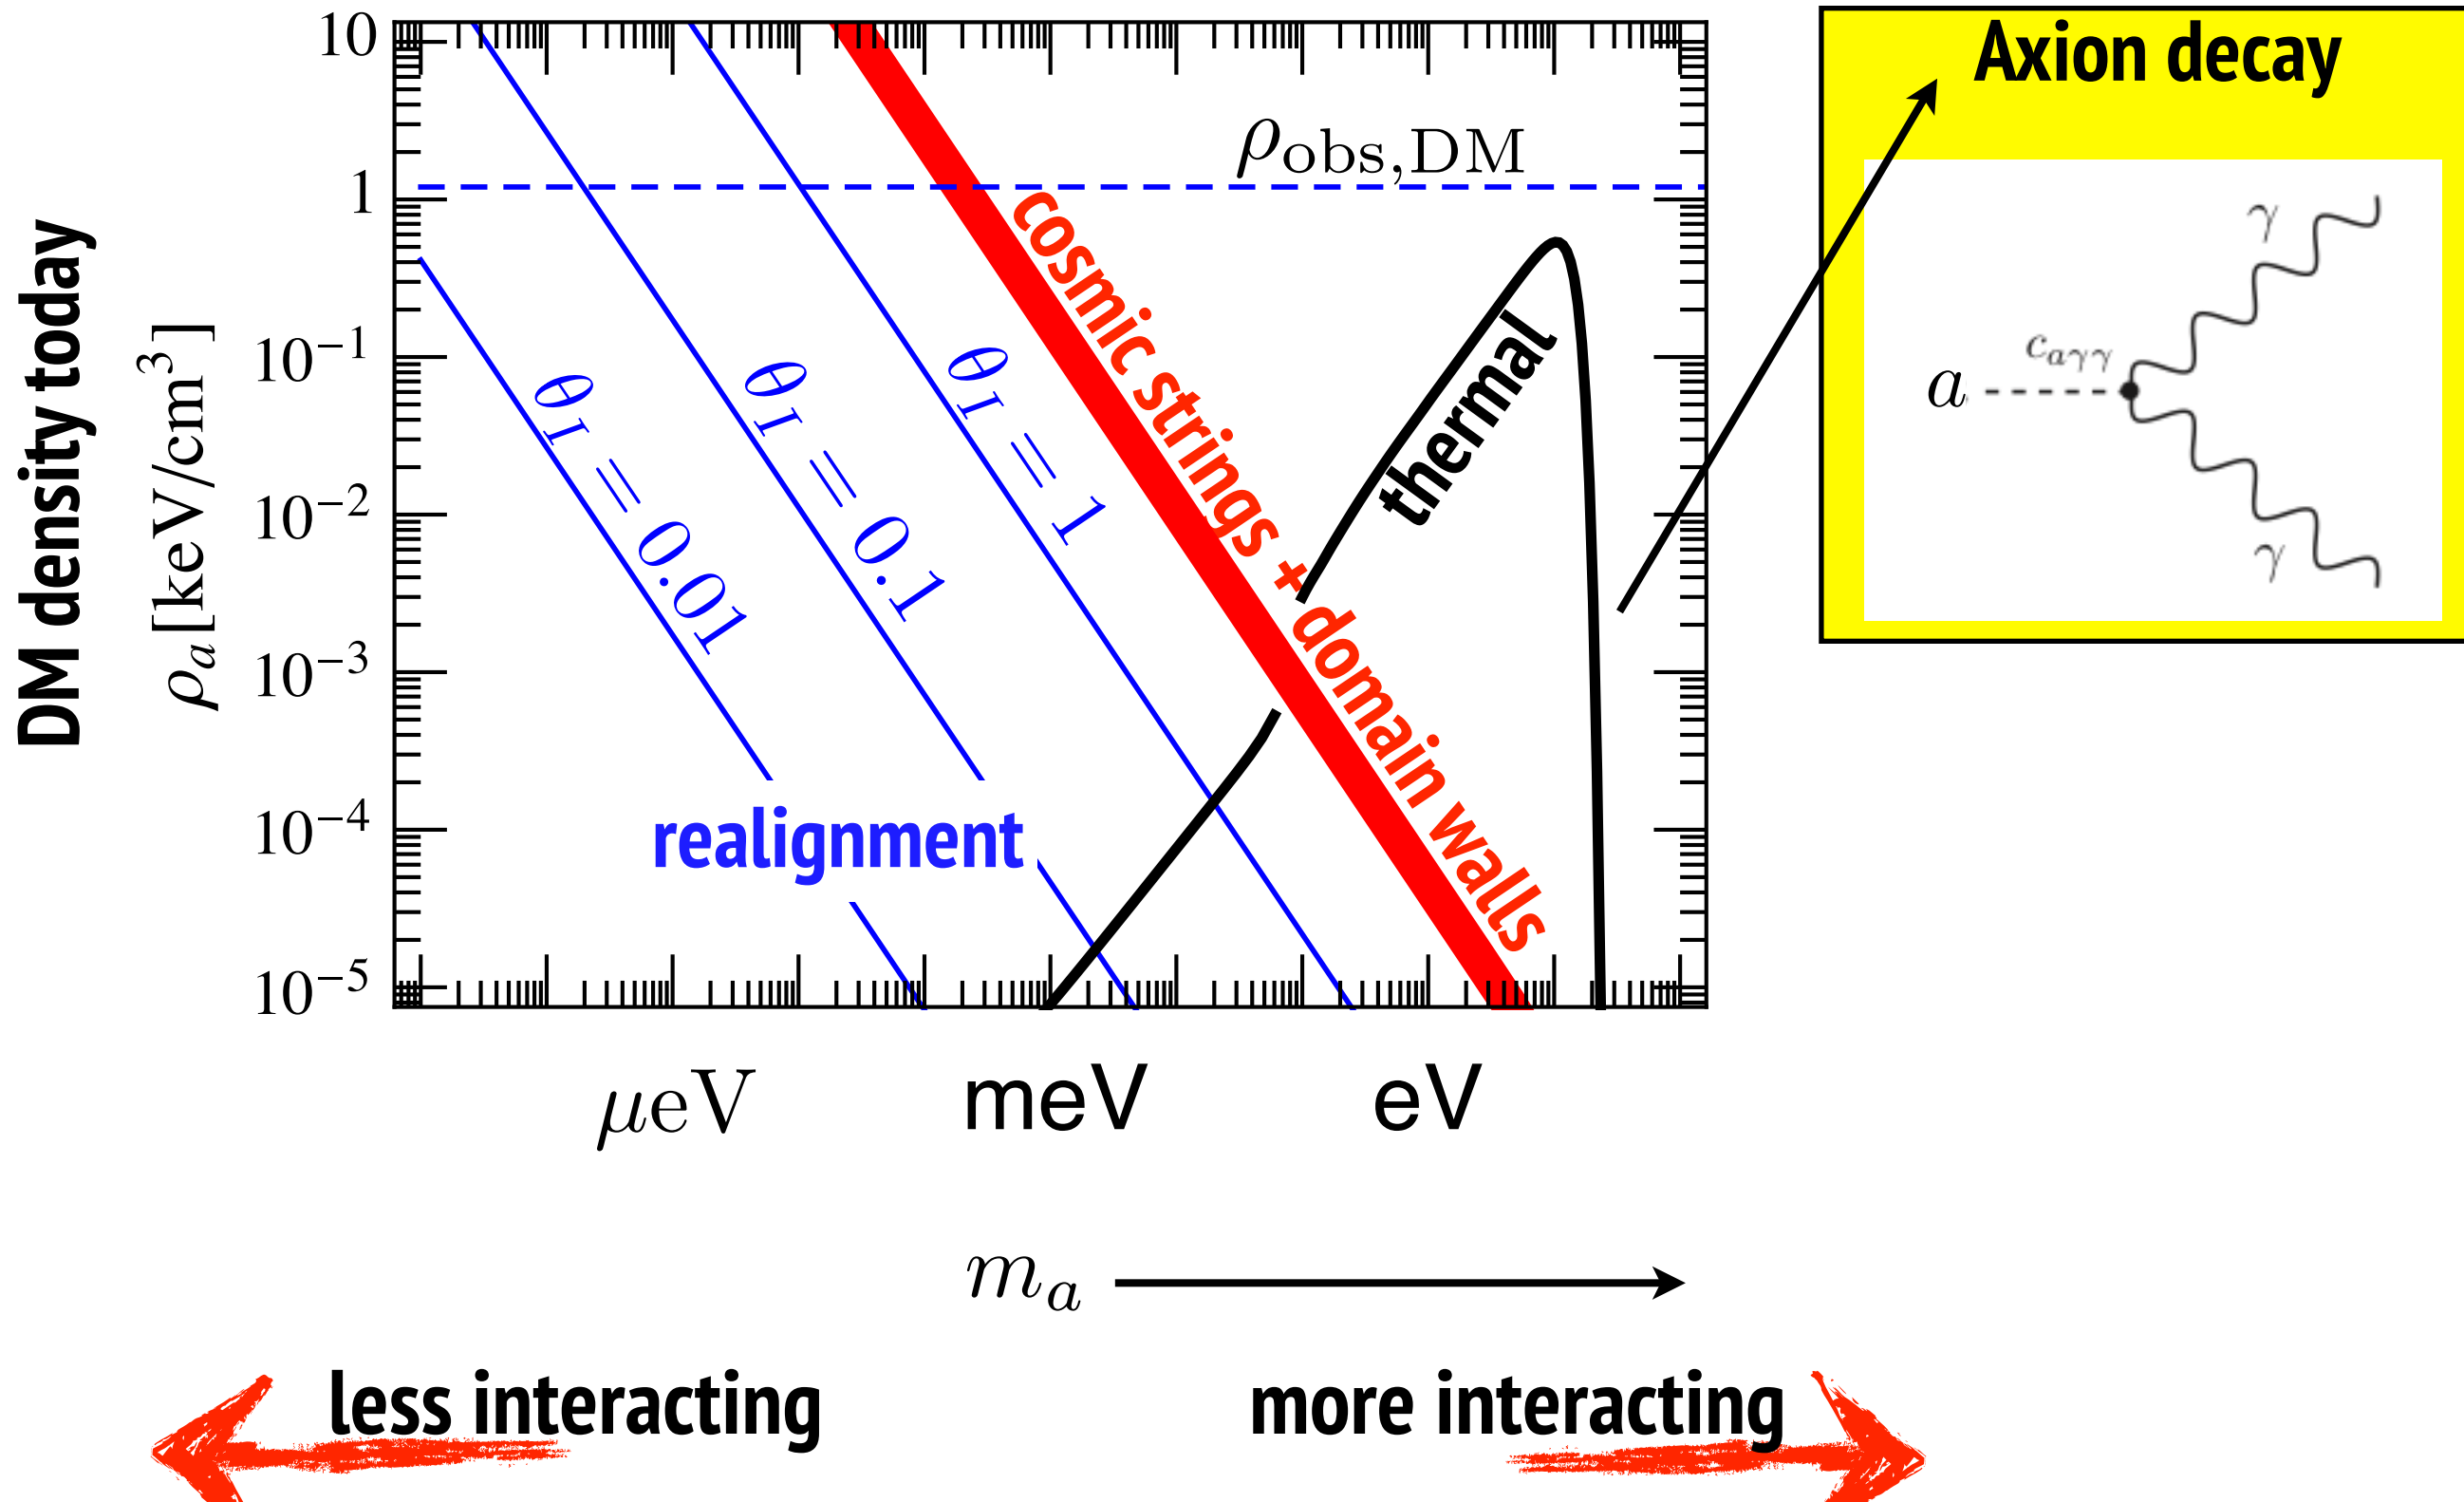

$$g_S(T_0) (R_1 T_1)^3 = g_S(T_0) (R_0 T_0)^3$$

Compute $\rho_a(\text{today}), \Omega_{\text{DM}} h^2 = \frac{\rho_a(\text{today})}{\rho_c}$

As a function of θ_1, f_a **and** θ_1, m_a

$$M_p = 1.22 \times 10^{19} \text{ GeV}$$

Axion DM, how much

Length scales

- Time scale

$$3H(T_1) = m_a(T_1) \quad t_1 \sim \frac{1}{2H_1}$$

- Horizon size (shorter wavelengths decay)

$$L_1 = 2t_1 \sim \frac{1}{H_1}$$

- Full Axion DM in this model $f_a \sim 10^{11} \text{ GeV}$

$$T_1 \sim 1.5 \text{ GeV} \left(\frac{10^{11} \text{ GeV}}{f_a} \right)^{0.16}$$

- Horizon scale at t_1

$$L \sim 10^4 \text{ AU} \quad (\text{comoving})$$

today corresponds to distances \sim Oort cloud

SCENARIO I (N=1): axion evolution around t1

Strings

Dark matter density, inhomogeneous at comoving mpc scales

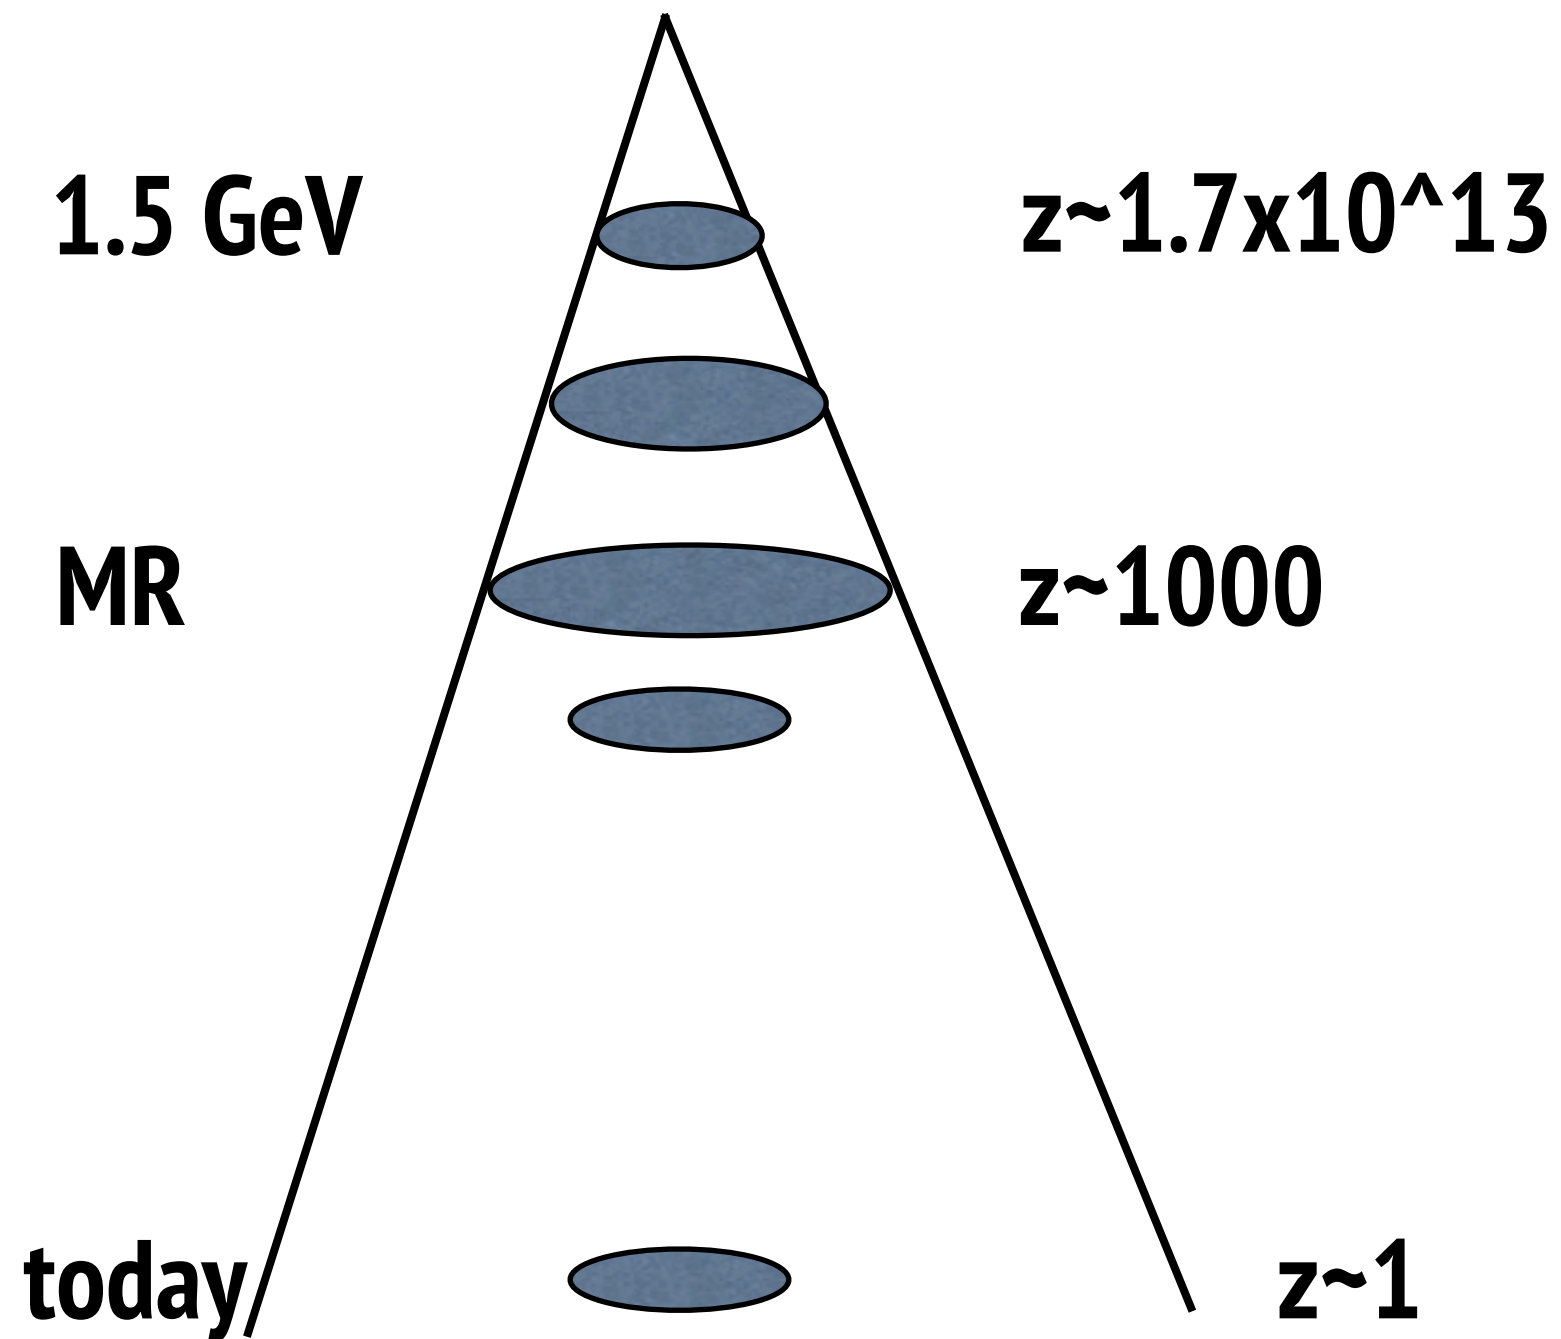

final overdensity $\frac{\rho - \langle \rho \rangle}{\langle \rho \rangle}$

→ **minicluster seed!**

do mc's survive?

Minicluster size

They expand with the Universe until \sim Matter-radiation equality ($z \sim 1000$)

$$L \sim \mathcal{O}(1) \text{A.U.}$$

Prob: Relic abundance calculation

DM density can be obtained from numerical simulations

We usually split it into two pieces:

- averaged misalignment

$$\langle \rho_a \rangle_{\theta_1} = \int \frac{d\theta_1}{2\pi} \rho_a(\theta_1)$$

- axions radiated from topological defects

(extrapolated from simulations) [work in progress]

Axion DM, how much

Axion dark matter

f_a [GeV]

- Axion DM scenarios

m_a [eV]

Initial conditions set by :

Inflation smooth

$$\Omega_{\text{aDM}} h^2 \simeq \theta_I^2 \left(\frac{80 \mu\text{eV}}{m_a} \right)^{1.19}$$

**Phase transition (N=1)
strings+unstable DW's**

SCENARIO I, N=1

$$\frac{a}{f_a} = N\theta$$

SCENARIO I, N>1, Domain Walls stable -> cosmological disaster

SCENARIO I, N=1

$$\frac{a}{f_a} = N\theta$$

SCENARIO I, N>1, break slightly degeneracy (but tuning...)

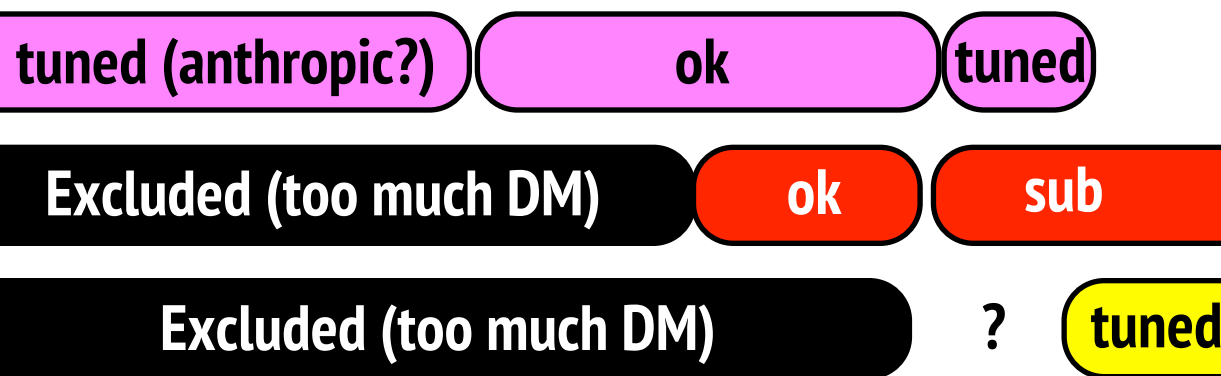

Axion dark matter

f_a [GeV]

- Axion DM scenarios

m_a [eV]

Initial conditions set by :

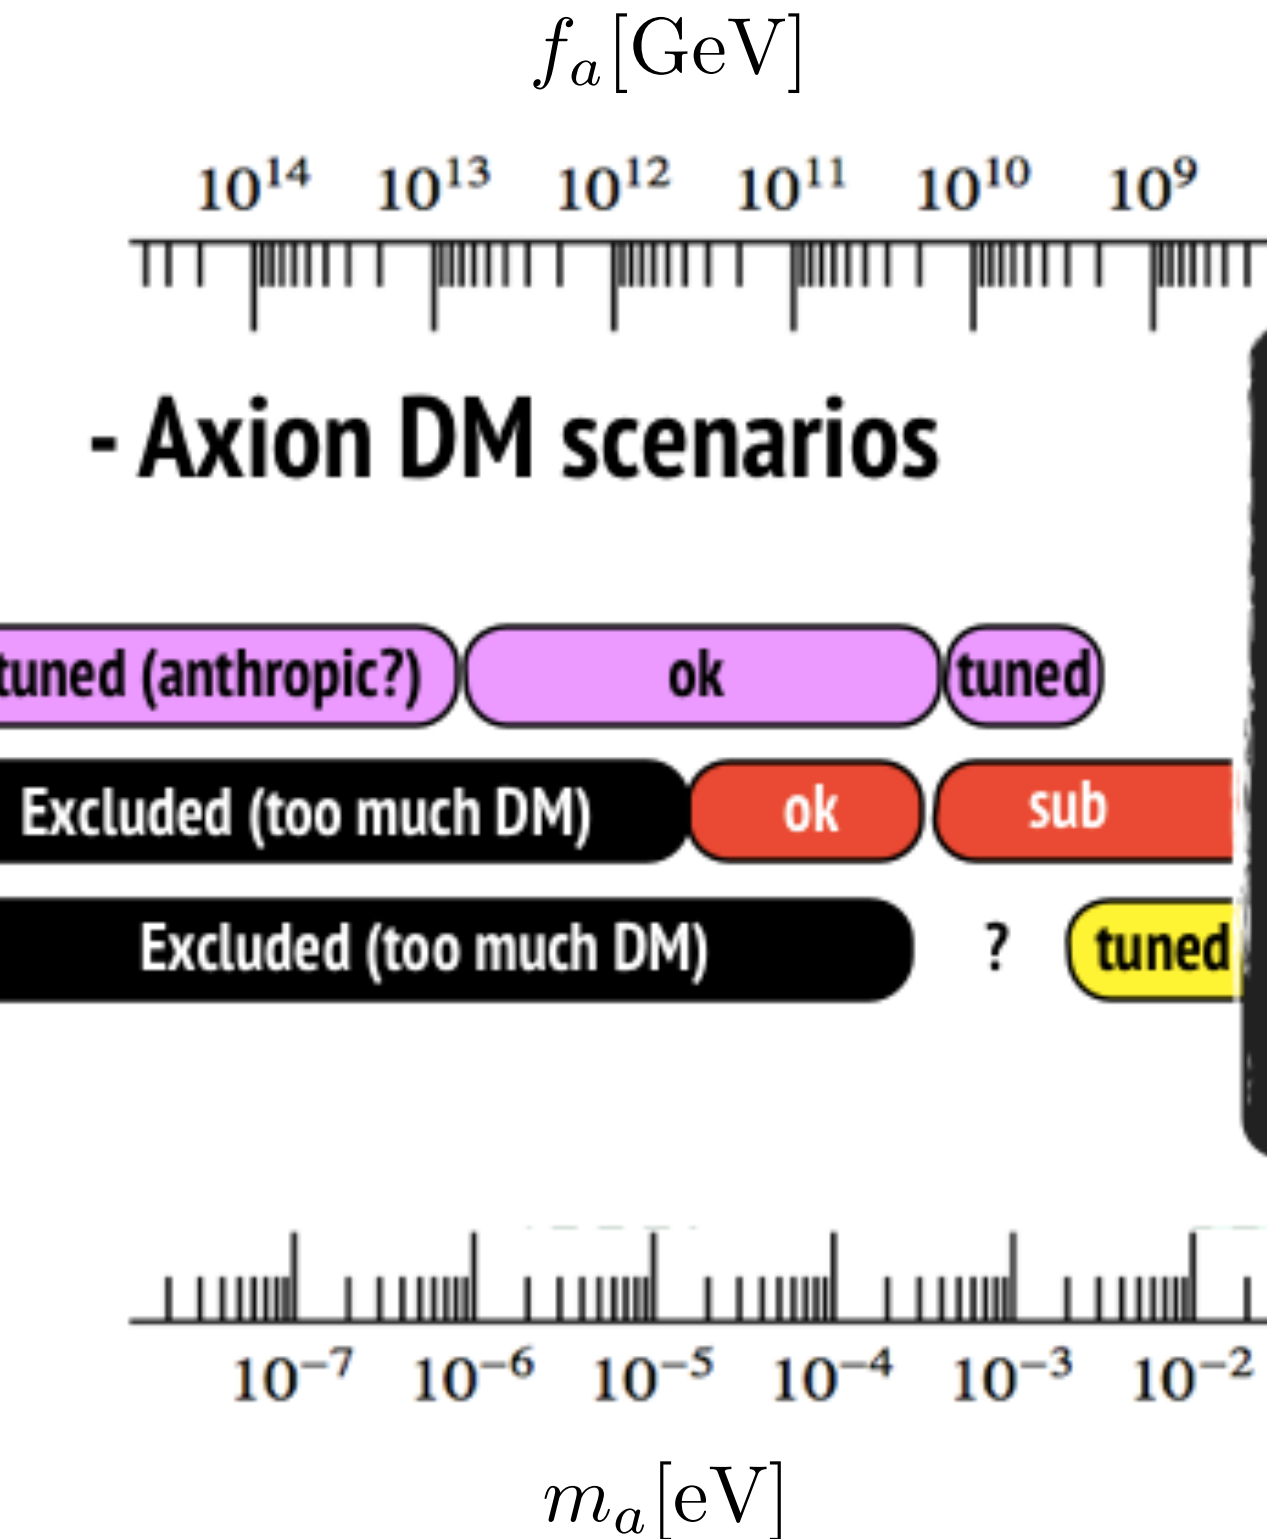

Inflation smooth

$$\Omega_{\text{aDM}} h^2 \simeq \theta_I^2 \left(\frac{80 \mu\text{eV}}{m_a} \right)^{1.19}$$

Phase transition (N=1)
strings+unstable DW's

Phase transition (N>1)
strings+long-lived DWs

Conclusions

- Some axion DM is inevitable
- DM ab. depends on i.c. and f_a
- Some scenarios “excluded”

- standard thermal history
- extrapolations
- isocurvature constraints

- $f_a \sim 10^{11}$ GeV favoured (?)
- larger f_a possible (anthropic)
- much do to!
